This property rights solution applied not merely in general but even to such apparently intractable problems as allocating electromagnetic spectrum to radio broadcasters: 'there can be little doubt that, left to themselves, the courts would have solved the problems of the radio industry in much the same way [by defining and enforcing property rights] as they had solved similar problems in other industries' (Coase, 1959, p. 30). Other interested parties were less sanguine. Chief Justice Taft, for example, resolutely 'dodged the radio question. I have refused to grant writs and have told the other justices that I hope to avoid passing on this subject as long as possible' (Coase, 1959, p. 30).

Indeed, what would the courts, left to themselves, have done? Taft was baffled by the radio question because property rights were ill-defined and the courts did not know how to define them. Awaiting a workable definition of property rights in electromagnetic spectrum – with the help of economists, lawyers, engineers, or managers – a property rights 'solution' remained elusive.

As Arthur DeVany put it, 'the real stumbling-block to a market system of spectrum allocation is the interference problem. The spectrum is a multidimensional space; signals propagate indefinitely in the frequency, spatial, and time domain' (1998, p. 169). The team of DeVany, Ross Eckhart, Dan O'Hara, Charles Meyers, and Richard Scott (three economists, a lawyer, and a physicist) turned their attention to this matter in 1969. Their best efforts to define property rights that would be 'exclusive, predictable, capable of subdivision, enforceable and flexible' (1998, p. 169)

notwithstanding, DeVany now concedes that their 1969 definition was merely a template and needed further refinements (1998, p. 169).

Indeed, going beyond the definition of property rights, there is a further problem: how to devise an auction? Although DeVany avers 'that our model has been used to privatize the spectrum in New Zealand, Australia, and Latin America' (1998, p. 168), Preston McAfee and John McMillan maintain that 'simultaneous single-round, sealed-bid auctions were used in New Zealand for spectrum licenses and in Australia for satellite-television licenses with disappointing results: low revenues and inefficient license allocations' (1996, p. 162). New developments in auction theory, which did not take shape until the 1980s and 1990s, were also needed. The simultaneously ascending auction was adopted by the FCC in the 1990s to auction spectrum for personal communications services: mobile telephones, two-way paging, portable fax machines, and wireless computer networks. Some judge that auction to be a 'success' (McAfee and McMillan, 1996, p. 163), but the actual sale of spectrum turned out to be 'more complicated that anything in auction theory' (McAfee and McMillan, 1996, p. 171).

Merely to conduct an auction ought not to be confused, moreover, with full privatization. In the US the FCC remains an active player in the management of spectrum. The upshot is that defining and enforcing property rights for some resources is a daunting exercise. Politics often continue, usually with the active participation of the key players. Realpolitik and partial privatization are evidently bedfellows.

Overreaching

The modern corporation

Might the salient features of the modern corporation be explained in property rights terms? Harold Demsetz took this position. Upon observing that there are 'significant economies of scale in the operation of large corporations … [and] that large requirements for equity capital can be satisfied more cheaply by acquiring the capital from many purchasers of equity shares' (1967, p. 358), Demsetz described the modern corporation in the following property rights terms: (1) efficiency is realized by delegating effective ownership to the management; (2) shareholders are essentially lenders of equity capital; and (3) limited liability relieves shareholders of the need to carefully examine corporate liabilities and the assets of other shareholders (as they would need to under partnership law).

This property rights interpretation of the modern corporation over-reaches in the first two respects. First, to suggest that diffuse ownership is responsible for delegation, whereupon the 'management group becomes the *de facto* owners' and that ownership is 'legally concentrated in management's hands' (Demsetz, 1967, p. 358) is incorrect. For one thing, delegation is observed in large corporations whether there are many or few owners of equity shares. For that matter, delegation is observed in every large organization – public, private, nonprofit. Well-known limits on the span of control (from organization theory) rather than the economics of property rights are responsible for that result. Additionally, of the three rights of ownership – the right to use, transform, and appropriate the income from an asset – the management is never delegated this last. Equity is the residual claimant.

Second, to describe shareholders as 'lenders' of equity capital is misleading. Debt and equity are not merely instruments of finance; they are also instruments of governance. If shareholders are merely lenders, why not just sell collateralized bonds? Or why not loans from the banks? It is not for naught that equity investors, who invest for the life of the firm and are residual claimants, are awarded control of the board of directors (Fama and Michael, 1983). The efficiency logic of debt and equity is usefully viewed as a governance issue (Williamson, 1988).

Russian privatization

The architects of privatizing Russian industry in the early 1990s appealed to the modern property rights theory of Sanford Grossman and Oliver Hart (1986) to urge mass and rapid privatization of all sectors of Russian industry (Boycko et al., 1995). The overarching theory was this: 'When property rights over a productive asset are clearly specified, and the person who decides how to employ his asset bears full costs and enjoys the full benefits of employment, he puts the asset to its most productive use' (Boycko et al., 1995, p. 19). Upon privatizing two-thirds of Russian industry in June 1994, Boycko et al. boldly declared that privatization had been brought to a 'triumphant completion' (1995, p. 8).

Subsequent events have been unkind. Although it may be unduly pessimistic to view Russian privatization as a failure (Braguinsky, 1999; Black et al., 1999), it is undisputed that Russian privatization has not been a triumphant success.

Errors of two kinds explain the premature pronouncement of success. First, the property rights theory of the firm suppresses problems of *ex post* governance by assuming costless renegotiation. That has analytical advantages, but it is also disconnected from reality. Had Boycko et al. inquired into contract implementation, they would have discovered that the efficacy of privatization varies, working much better in some industries than others (Williamson, 1976; Goldberg, 1976; Priest, 1993). Second, Boycko et al. never faced up to lapses in the laws and, even more, their efficacious enforcement in Russia. Failures to look beyond the immediate award of property rights and examine the needs for *ex post* governance support and effective legal recourse turned out to be fateful.

As with the allocation of electromagnetic spectrum and interpreting the modern corporation, so too with Russian privatization. Thus although property rights reasoning is pertinent to all, the economics of property rights is a self-limiting perspective. Awaiting a unified theory of economic organization, which is not in prospect, the application of several lenses – to include an examination of hazards that beset *ex post* governance and the condition of the institutional environment – has a lot to recommend it.

Conclusions

The economics of property rights is unarguably important. Were it that the Socialist Controversy in the 1930s was less preoccupied with technicalities (such as marginal cost pricing) but addressed itself more to an assessment of the

property rights differences between capitalism and socialism, the field of comparative economic systems would have developed very differently (Demsetz, 1998). But while property rights are crucial, they are not fully determinative of economic organization. To claim that efficiency will be realized upon defining and enforcing property rights simply overreaches. Not only can property rights be difficult to define, but best efforts at court enforcement can be costly. Also, property operates in combination with contract and organization.

Kenneth Arrow's remarks about externalities, market failures, and transaction costs help to restore perspectives: 'I contend that market failure is a more general category than externality [and, because] market failure is not absolute … , it is better to consider a [still] broader category, that of transaction costs, which in general impede and in particular cases completely block the formation of markets' (1969, p. 48). Transaction cost is an inclusive concept that applies to property, contract, and governance.

Editor's Note

Transaction costs (basically, the costs of entering a market) continue to figure prominently in economic thinking. Some recent exemplars of research in this area include: Argyres and Zenger, 2012; Williamson, 2010; Coggan et al., 2010; Tadelis and Williamson, 2012.

Abstract

Transcranial direct current stimulation (tDCS) may be able to affect language functions, over both shorter (minutes) and longer (hours to perhaps months) intervals. Individual differences in psychological capacities, neurophysiology, and neuroanatomy make within-subjects, repeated-measures designs ideal for tDCS studies using present-day methods. True 'sham' stimulation may not be possible at higher levels of current. Designs that take these factors into account, coupled with improved methods of focusing current and orchestrating when and where it is applied, will likely strengthen the usefulness of tDCS for investigating language functions and improving them.

Introduction

There have been several recent excellent reviews of the use of transcranial direct current stimulation (tDCS) to alter various aspects of language (Chrysikou and Hamilton, 2011; Floel, 2012; Fridriksson et al., 2012; Monti et al., 2012; Schlaug et al., 2011). Rather than simply update these reviews, this article will provide a broader perspective on current and potential applications of tDCS to language functions.

Ideally, the rational use of tDCS would be guided by a thorough knowledge of its effects on neural tissue and by knowledge of how language and related processes are generated by the brain. But we are far from having such knowledge. The best we can do at present is make educated guesses and advance by trial and error. This article is an attempt to outline what knowledge we do have and how we might best proceed to test for the effects of tDCS on language. In this article, a reference to 'language' will generally mean not just language itself, but also speech and all the processes associated with language comprehension, usage, and production.

Neural Effects of tDCS

To a first approximation, tDCS as it usually is employed (with 1–2 mA stimulation levels) generates electric fields that are thought to range from 0.2 to 1.5 volts per meter ($V\,m^{-1}$) in regions of the cortex and subcortical structures (Parazzini et al., 2011). Initial studies in animals and humans suggested a straightforward consequence: Tissue underneath the anodal electrode was stimulated, whereas tissue underneath the cathodal electrode was inhibited (Bindman et al., 1964; Creutzfeldt et al., 1962; Matsunaga et al., 2004; Nitsche and Paulus, 2000, 2001; Purpura and McMurtry, 1965). However, with increasing knowledge of how such relatively weak electric fields might affect neural tissue has come an appreciation that the "anodal stimulatory/cathodal inhibitory" rule likely is a somewhat misleading simplification. This section, on the possible neural bases for tDCS effects, is organized primarily by spatial scale.

Molecular and Membrane Effects

Weak electric fields are thought to exert their initial effects at the molecular level by displacing intracellular ions and thereby altering neuronal resting membrane potentials (Ruffini et al., 2012). Typical currents delivered by tDCS at the scalp (1–2 mA) are severely attenuated by the time they reach the brain (Miranda et al., 2009, 2013), and the low field intensities they produce probably cannot directly stimulate cerebral structures (Bikson et al., 2004; Roth, 2009), although see (Feurra et al., 2011). Indeed, each volt per meter of field intensity can produce on average only around 0.3 mV of membrane polarization (Bikson et al., 2004; Roth, 2009). This is much less than the tens of millivolts required to produce action potentials. Thus, tDCS generally is regarded as a modulatory technique that requires ongoing neural activity to produce effects. However, cortical morphology may cause current to be distributed unevenly beneath the electrodes, with cortical surface density in some areas 10- to 100-fold higher than the average density beneath the electrode (R. Sadleir, personal communication, April 2013). Thus, we cannot rule out the possibility that tDCS might trigger action potentials in some instances.

The immediate 'online' effects (during stimulation) are thought to depend on transient changes in resting membrane potential. This is borne out by studies in which pharmacological blockade of ion channels, but not *N*-Methyl-D-aspartate (NMDA) or γ-Aminobutyric acid (GABA) receptors, abolished changes in cortical excitability that coincide with stimulation (Nitsche et al., 2003, 2004a). Aftereffects (or off-line effects) of tDCS can also persist for minutes to hours (Bindman et al., 1964; Nitsche and Paulus, 2001), and these long-term changes likely also involve molecular-level mechanisms (Stagg and Nitsche, 2011). These may include dependence on NMDA receptors (Liebetanz et al., 2002; Nitsche et al., 2004b); protein synthesis (Gartside, 1968a,b); changes in intra- and extracellular calcium levels (Islam et al., 1995a); early gene expression (Ranieri et al., 2012); alterations of dendritic spines (Jiang et al., 2012); and the modulation of intracellular messengers implicated in calcium signaling and neuroplasticity, such as protein kinase C (Islam et al., 1995b), cyclic adenosine

monophosphate (cAMP) (Hattori et al., 1990; Moriwaki et al., 1994), myoinositol (Rango et al., 2008), and brain-derived neurotrophic factor (BDNF) (Fritsch et al., 2010). A growing body of evidence, therefore, supports the notion that Long Term Potentiation (LTP)-like mechanisms, long considered important for learning and memory (Malenka and Bear, 2004; Owen and Brenner, 2012), may be responsible for effects that begin a few minutes after the onset of tDCS and persist after stimulation ends.

Despite strong evidence that the aftereffects of tDCS involve synaptic mechanisms, alternatives have been proposed (Ardolino et al., 2005). These include the nonsynaptic modulation of axonal excitability, intra/extracellular pH changes induced by water electrolysis, and even the direct alteration of transmembrane protein conformation and migration within the cell membrane, analogous to gel electrophoresis. This mechanism is of particular interest in light of evidence that during synaptic transmission, ion fluxes through postsynaptic receptors produce electric fields that may clear neurotransmitters from or draw them toward the synaptic cleft via electrodiffusion (Savtchenko et al., 2004; Sylantyev et al., 2008, 2013). They may even cluster postsynaptic α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors across from vesicular release sites (Savtchenko et al., 2000).

Cellular Effects

At the cellular level, changes in membrane potential are usually not distributed evenly across a single neuron. Anodal fields oriented radially to the cortical surface, and therefore parallel to the axodendritic axes of pyramidal cells, tend to depolarize somas and will actually hyperpolarize apical dendrites (Radman et al., 2009). The reverse is true for cathodal stimulation. However, the fields produced by tDCS also tend to have a significant tangential component (Miranda et al., 2013) that does not polarize somas but, instead, hyperpolarizes or depolarizes fibers running parallel to the cortical surface, which then facilitates or depresses synaptic efficacy (Rahman et al., 2013).

This raises the question of why differential polarization of neuronal compartments does not have opposing effects that cancel out net modulation of the cell. For anodal stimulation at least, the answer may be due to the possibility that, in some instances, hyperpolarized dendrites can depolarize neurons. Hyperpolarization-activated cyclic nucleotide-gated (HCN) channels are richly expressed in apical dendrites and counteract membrane hyperpolarization by admitting a sodium and potassium current (Kase and Imoto, 2012), which may explain why differential polarization within neurons enhances, rather than interferes with, neural excitability under tDCS. Moreover, these channels are believed to help induce neuronal oscillations and to facilitate firing-pattern transitions from single spiking to bursting (Benarroch, 2013) when, for instance, neuronal action potentials backpropagate into dendrites. This may be an important way for seemingly negligible changes in membrane potential to amplify and synchronize ongoing neural activity (Tse, 2013: pp. 89–103).

While effects on pyramidal cells have received a great deal of attention, tDCS likely affects other cell types. Recent calculations using cable theory suggest that tDCS may also act on glial cells (Ruohonen and Karhu, 2012), although this has not been confirmed experimentally (Roth, 2012). Moreover, weak electric fields are known to enhance cell motility (Heo et al., 2012) and neurite outgrowth (Koppes et al., 2011). Field orientation may even alter neuronal precursor migration and differentiation during development (Ariza et al., 2010; Yao et al., 2009).

Both excitatory and inhibitory interneurons may also be affected by tDCS (Nitsche et al., 2005). As with pyramidal cells, their stimulation thresholds and polarizability can vary as a function of morphology (Radman et al., 2009) and cortical depth (Purpura and McMurtry, 1965). Additionally, pharmacological and magnetic resonance spectroscopy (MRS) studies suggest that tDCS alters cortical and even subcortical neurotransmitter levels of dopamine (Kuo et al., 2008; Nitsche et al., 2006; Monte-Silva et al., 2009; Nitsche et al., 2009; Tanaka et al., 2013), acetylcholine (Kuo et al., 2007), and GABA (Stagg et al., 2009). For instance, tDCS effects on cortical GABA levels may enhance cortical excitability via pyramidal cell disinhibition. To that effect, a recent neural modeling study showed that decreasing extrasynaptic GABA levels induced continuous subthreshold membrane depolarization that did not change spontaneous activity but did enhance pyramidal responses to subsequent inputs (Hoshino, 2011). Since different classes of GABAergic interneurons target specific cell compartments (e.g., dendrites, somas) (Royer et al., 2012), tDCS may alter how they regulate distinct aspects of neural activity (e.g., pyramidal bursting, phase synchronization).

Network Effects

Evidence suggests that weak electric fields produce small changes in the spike timing and firing patterns of individual neurons, which may then be amplified by the dynamic activity and mass effects of the neural networks in which they are embedded (Reato et al., 2010). Although it is well established that neurons have subthreshold sensitivity to very low voltage gradients of around 1 V m^{-1}, networks might be even more sensitive to field modulation than single neurons (Francis et al., 2003). This likely results from recurrent excitatory loops within networks that contain locally coupled inhibitory activity (Reato et al., 2010; Weiss and Faber, 2010). In fact, some networks, by virtue of their uncommonly uniform cell orientation and tight cell packing, can have especially low stimulation thresholds. Hippocampal region CA1, for instance, responded to fields as small as 0.140 μV mm^{-1}, an order of magnitude lower than what was previously thought possible. The adjacent but somewhat sparser and less cytoarchitecturally homogeneous CA3 region did not show this enhanced susceptibility (Francis et al., 2003). Regional discrepancies of this kind are likely to figure prominently in the myriad interindividual differences in tDCS responsiveness that we consider further below.

Many of these effects occur endogenously through ephaptic interactions, by which spatially proximate groups of neurons produce extracellular potentials that then feedback and synchronize their own activity (Anastassiou et al., 2011). Recent work shows that (at least in ferret visual cortex) weak DC fields of similar strength to *in vivo* ephaptic potentials can enhance, while both sinusoidal and naturalistic waveforms can entrain, the activity of cortical networks (Frohlich and McCormick, 2010). By showing how waveforms that closely resemble those produced *in vivo* can modulate network activity, this work raises

the possibility that tDCS is engaging a very important component of neural processing (Ruffini et al., 2012; Weiss and Faber, 2010).

These findings seem to lend credence to reports that tDCS and alternating current (tACS) can modulate and perhaps entrain cortical oscillations in humans (Antal et al., 2004; Garcia et al., 2011; Jacobson et al., 2011; Kanai et al., 2010; Siebner and Ziemann, 2010; Zaehle et al., 2010), although see Brignani et al. (2013), especially when the stimulation matches the endogenous frequency (Merlet et al., 2013; Neuling et al., 2013). Cortical oscillations may have an important relation to the substrates of speech and language processing (Giraud and Poeppel, 2012), and so these emerging strategies may prove extremely influential.

Although not necessarily as a result of modulating oscillatory activity (Stagg and Nitsche, 2011), tDCS can affect neural processing within both local and more distributed, higher-level networks. Many studies have shown perceptual, behavioral, and excitability modulations in motor (Bergmann et al., 2009; Cambiaghi et al., 2010; Di Lazzaro et al., 2012; Galea and Celnik, 2009; Kwon et al., 2008; Monte-Silva et al., 2012; Polania et al., 2012), visual (Antal and Paulus, 2008; Chi et al., 2010), auditory (Ladeira et al., 2011; Zaehle et al., 2011), and somatosensory cortices (Dieckhofer et al., 2006; Marquez-Ruiz et al., 2011, 2012; Matsunaga et al., 2004; Ragert et al., 2008; Rogalewski et al., 2004). Various cross-modal interactions have also been affected following, for instance, stimulation in areas peripheral to those being directly engaged by a given task (Bachmann et al., 2010; Bolognini et al., 2011; Lapenta et al., 2012). This suggests that the effects of tDCS are less localized than might be hoped, despite recent attempts to optimize focality with various high-definition models and montages (Datta et al., 2013; Edwards et al., 2013; Huang et al., 2012; for recent reviews, see Bai et al., 2013; Bikson and Datta, 2012; Ruffini et al., 2012).

Indeed, stimulation of what was assumed to be relatively discrete cortical areas can induce changes in cortical blood flow across distant brain regions (Venkatakrishnan and Sandrini, 2012; Zheng et al., 2011). However, the widely distributed nature of many higher cognitive functions, such as language (Friederici and Gierhan, 2013; Price, 2012), may render this lack of focality more of a strength than a weakness.

Functional and Neuroanatomic Organization of Language Processes

The functional and neuroanatomic architectures of language introduce their own complexities into the possible effects of tDCS.

Functional Organization

Network Organization

The notion that language (in common with most if not all higher functions) is generated through a set of more-or-less independent subprocesses (or stages) is now both an empirical demonstration and, in some respects, an article of faith. In the current context, we must consider how such a complex network might be affected by an external perturbation such as tDCS. One complexity to bear in mind is that neither the subfunctions nor their products are always easily defined. Phonologic perception, orthographic identification, lexical semantics, phonologic production, and articulation have been relatively well identified and teased apart. But pragmatic intent, prelinguistic language (Jackendoff, 2002), and many processes encompassed by the term syntax may be less modular, or have more pervasive representations. Moreover, we should expect a high degree of rapid interconnectivity among various stages, not just feed-forwards, but also feed-backwards (Gordon, 1997).

In addition, it is generally appreciated that language as a whole is a subsystem embedded within, and responsive to, other systems of the mind. There is independent evidence, based mainly on function Magnetic Resonance Imaging (fMRI), for a "default network," an arousal/attentional network, and a cognitive control network (Bressler and Menon, 2010). All three are believed to underlie cognitive, and especially executive, functions considered important for language (Acheson and MacDonald, 2009; Gruber and Goschke, 2004; Ye and Zhou, 2009). These include working memory (Fuster and Bressler, 2012) and selective attention (Miller and Buschman, 2013) as well as potential interactions between automatic and controlled processing, for instance, during lexical–semantic retrieval (Hills et al., 2012; Hurks et al., 2004; Vannorsdall et al., 2012a,b) or language switching in bilinguals (Hervais-Adelman et al., 2011; Magezi et al., 2012). It is also possible that network hubs like the anterior insula and larger salience network may be critical for effectively switching between resting and executive networks (Menon and Uddin, 2010). Recent evidence suggests tDCS can modulate the functional connectivity of these networks (Keeser et al., 2011; Meinzer et al., 2012; Park et al., 2013; Pena-Gomez et al., 2012; Pereira et al., 2012; Polania et al., 2011; Sehm et al., 2012), which makes them attractive targets for study. And, regardless of whether language systems can be considered logically independent from these networks, they often have a close anatomic proximity if not dense interweaving and, perhaps even, physiologic interdependencies.

As is true of any complex system with multiple responsibilities, we might also expect to find trade-offs and conflicts. Strengthening a subfunction might paradoxically worsen overall network performance; inhibiting a subfunction might improve it. Moreover, the impairment or improvement at the network level may occur in subtle but important aspects of language processing. Anodal stimulation over right anterior temporal lobe and cathodal stimulation over the left anterior temporal lobe, for instance, have been shown to enhance creative problem solving (Chi and Snyder, 2012), insight (Chi and Snyder, 2011; Metuki et al., 2012), and mediated semantic priming (Weltman and Lavidor, 2013). Presumed interference with cognitive control processes via cathodal stimulation of the left dorsolateral prefrontal cortex (DLPFC) was found to facilitate the adoption of unconventional object uses (Chrysikou et al., 2013), enhance convergent thinking (Cerruti and Schlaug, 2009), and alter the cognitive strategies used to learn novel grammars (Friederici et al., 2013). Inhibition can also be used to enhance performance when stimulation of a given region is desired (e.g., DLPFC to facilitate working memory), but direct stimulation may produce complex interactions, for instance, due to the region's complex cell morphology or dynamic, reciprocal network

connectivity (Arnsten et al., 2012). For instance, Pope and Miall (2012) showed that cerebellar cathodal stimulation improved working memory performance, presumably by disinhibiting the prefrontal cortex (PFC). Via a potentially similar disinhibitory technique, cathodal stimulation of right Wernicke's area was used to enhance language comprehension in subacute stroke patients (You et al., 2011). Other studies have shown that cathodal stimulation can suppress competing channels and improve the signal-to-noise ratio during dichotic listening paradigms (Alexander et al., 2012) and attentional tasks (Weiss and Lavidor, 2012). Thus, the disinhibition of a cross-hemispheric, homologous structure or via two distant structures may offer an innovative way to explore the efficacy of indirect approaches to stimulation.

Within-Stage Processing

The situation is even more complex when we consider how tDCS might affect the operations within a processing stage. While no one can pretend to know the exact operations performed in any stage involved in language, there are empirical and theoretical hints as to the approximate kind of behaviors we can expect (Gordon, 1997).

At a fairly general level, it seems reasonable to distinguish between the dynamic patterns of electrochemical activity in a neural network, and the underlying neuroanatomic connections and synaptic weights that generate and support those patterns. It is tempting to imagine that psychological entities such as abstract letter identities, orthographic word forms, semantic features, and phonologic bundles are encoded as more-or-less discrete patterns of neuronal activity. We can also speculate more generally about the ability of a particular neural network to produce these patterns. One way of better formalizing and specifying these notions is to represent these psychological states as attractor states of neural activity (in some ways a more neurophysiologically grounded interpretation of earlier notions of nodes or resonant states, such as in Ratcliff (1978); see Gordon (1997) for a discussion). A specific word form or semantic feature would then be a specific attractor state that the network may achieve with appropriate inputs and internal connectivity. These attractor states, and the ghostly meaning that they convey, are not static. It is reasonable to imagine the concepts or entities that they represent gradually coalescing out of neural activity, and then dissipating when the stimulus is gone and intrinsic activity no longer supports the particular pattern (or gets replaced by a new one). Externally, this coalescence and dissipation would seem to correspond to the growth and decay of mental entities that has been delineated by other means (Hart et al., 1998).

From abundant psychological evidence, we can put some temporal boundaries on processing at these individual code levels. Phonemic and phonologic entities may be able to stabilize within tens of milliseconds. Orthographic and semantic ones probably take more on the order of hundreds of milliseconds (cf Hart et al., 1998).

In this conception, the neural network responsible for a particular code has many latent representations of specific, learned elements or features of that particular code. Active patterns of activity that are essentially orthogonal to each other might be expected to coexist to some extent within a single neural network. There are many potential reasons for real or virtual mutual inhibition and constraint (e.g., Reggia et al., 1992). Evidence for mutual competition between within-level representations might even serve as an important clue to the nature of the internal mechanics of these more elemental levels of processing.

To the extent this general understanding captures and explains the dynamic characteristics of the elements that make up language functions, it suggests ways in which the effects of tDCS and other manipulations might be observed. tDCS might alter such parameters as the depth (or height) of attractor states, the rate at which patterns evolve toward their end points, or the noisiness or meandering of the pattern-seeking process. It might also affect interactions among patterns as they evolve.

Although the myriad parameters at the single-neuron and network level seem daunting, it is also possible that they may blend into only a relatively few variables of global relevance. Profound differences in behavioral functions might then be affected by relatively simple alterations, perhaps analogous to the way differences between normal and aphasic naming have been attributed to quantitative rather than qualitative differences (Dell et al., 1997).

Neuroanatomic Organization

Some processing stages seem to correspond to relatively distinct neuroanatomic regions; for others, the correspondence is far from clear (Price, 2012). In the clearest functional–neuroanatomic correlations, such as lesions that affect orthographic word codes (the visual word form), the cortical areas involved can be as small as a few square centimeters (Dehaene and Cohen, 2011). But even these dependencies may not be as absolute as classical anatomy assumed. There may be latent representations of functions in the tissue adjacent to the most critical areas, as evidenced by the relatively rapid restitution of functions that can occur after focal lesions (cf Gordon et al., 1999).

What complicates the functional–neuroanatomic correlation of language is evidence that many if not most human beings have a variable degree of duplication of language and other functions across the hemispheres (Hugdahl and Westerhausen, 2010). And this brings us to the even broader question of individual differences.

Individual Differences

Individual Differences in Language Capabilities

There are vast differences in the language capabilities of different individuals, even of putatively 'normal' or 'neurotypical' people (Chandrasekaran et al., 2010; Shao et al., 2012; Sontam et al., 2009; Szenkovits et al., 2012; Yap et al., 2012). Interindividual differences can be two- to threefold or more in magnitude. In addition, many psychological functions are notoriously variable over time, even within the same individual (Dykiert et al., 2012; Evans and Demuth, 2012; Hayiou-Thomas et al., 2012; Heyanka et al., 2013; Niemela et al., 2013; Ode et al., 2011; Pnevmatikos and Trikkaliotis, 2013; Small et al., 1995; Vandermorris et al., 2013). Furthermore, the level of particular abilities within a single individual is not necessarily predictive of the level of other abilities (Schretlen et al., 2008; Selnes and Gordon,

1999). The basis or bases of inter- and intra-individual variability could offer important clues to the origin of these functions. However, they are also a major experimental barrier. As a result, many language functions that are fine-grained enough to be interesting can only be studied with adequate precision using within-subjects designs.

It is also likely that there are differences in the routes or mechanisms through which different individuals process language information (Caplan, 1988) or, probably for some functions, even in the same individual at different times. Given that interindividual variability in psycholinguistic processing mechanisms has been found in college undergraduates (Chiarello et al., 2012; Prat and Just, 2011; Welcome et al., 2011), one can reasonably expect that the broader population is likely to show greater differences (cf (Henrich et al., 2010; Gutchess et al., 2010)), especially persons with developmental or acquired disorders (Abbeduto et al., 2007; Bishop and McArthur, 2005; Borella et al., 2011; Budden, 2012; Elsabbagh et al., 2011; Gooch et al., 2012; Haley and Martin, 2011; Marinus and de Jong, 2010; Pellicano, 2010; Staiger et al., 2012; Venker et al., 2013).

Individual Differences in Neuroanatomy and Neurophysiology

We are only just beginning to appreciate that individuals can show remarkable heterogeneity of even basic neurophysiologic parameters, such as NMDA receptor allotypes (Sanz-Clemente et al., 2013) and dopamine-related genes (Wong et al., 2012), which may well be important in tDCS effects. What has long been appreciated are individual differences in regional anatomy as defined by cytoarchitectonics, with surface area differences of up to threefold, in regions including visual cortex (Amunts et al., 1999; Dougherty et al., 2003; Van Essen et al., 1984; Van Essen et al., 2001), Broca's area (Amunts et al., 1999; Keller et al., 2009; Sherwood et al., 2003), the inferior parietal (Bogolepova and Malofeeva, 2004; Caspers et al., 2006) and the prefrontal cortices (Fornito et al., 2008), and even subcortical limbic areas (Amunts et al., 2005; Bogolepova and Malofeeva, 2008). The basis and significance of most of these differences are still unknown, although some have been correlated with individual abilities (see Kanai and Rees (2011) for a review), and some may be a product of practice, not inheritance (Li et al., 2010).

Furthermore, there are great interindividual differences in the pattern of cortical folding with respect to the skull (Derrfuss et al., 2009; Keller et al., 2007; Mangin et al., 2004). Since tDCS must penetrate scalp, skull, and CSF to affect brain tissue, the variability across individuals in the amount of hair, the thickness of the scalp and subcutaneous tissues, the thickness of the skull, the presence of sutures and penetrating veins, and the amount of CSF are also relevant. Even montages that deliver relatively focal current are at times unable to produce the same effect across individuals without more than doubling the electric field strength (Edwards et al., 2013). Moreover, since the current in tDCS is volume-conducted and can be shunted by other structures, any given individual presents a very complicated situation in terms of just where current applied to the scalp will wind up in the brain, how much current will reach any one location, and how effective it will be upon arrival (Datta et al., 2009; Sadleir et al., 2012).

How Reliable Are Reported tDCS Effects?

One reason we have not tried to draw broad conclusions in this article about the effects of tDCS on language functions is our concern about the reliability of results reported in the literature. This is not because of evidence specific to tDCS itself. To our knowledge, there are no published efforts to directly replicate any language-related tDCS studies, although aspects of some results have failed to replicate (Huey et al., 2007; Koenigs et al., 2009). Rather, there simply is no reason to believe that tDCS studies of language will be more reliable and reproducible than those in other areas of psychological and cognitive neuroscience (Button et al., 2013; Uttal, 2013; Yong, 2012; Makel et al., 2012), or of science in general (Ioannidis, 2012; Prinz et al., 2011).

Considerations for Future tDCS Studies

This article leads us to suggest the following prescriptions and cautions for future tDCS studies of language:

1. While studies of tDCS have appropriately focused on possible modulatory effects, what is known of tDCS neurophysiology suggests that a search for possible effects on item representations, interitem competition, and network-level parameters and dynamics may also be fruitful.
2. When designing studies using tDCS to alter behavior, investigators must always consider the influence of homeostatic effects on neuroplasticity. There has been little exploration of state-dependent effects when using tDCS to alter language function, but tDCS effects on the motor cortex might provide guidance. There, prestimulation neural network activity powerfully modulates the strength and direction of electrophysiological responsiveness to stimulation (Fricke et al., 2011; Monte-Silva et al., 2010). For instance, neural excitability that has been altered by noninvasive brain stimulation, or even by mental states or behaviors, may determine subsequent responsiveness to tDCS (Ridding and Ziemann, 2010; Siebner et al., 2004). Cerebral tissue has a number of metaplastic mechanisms (Hulme et al., 2013; Stagg and Nitsche, 2011). In general, neural tissue is less excitable following excitatory stimulation, and less likely to be depressed after being inhibited. Such mechanisms demonstrate the importance of controlling prestimulation activity, and they suggest that the timing of stimulation will be crucial for maximizing treatment effects. For example, somatosensory paired association was enhanced following anodal tDCS but inhibited by concurrent stimulation (Nitsche et al., 2007). When anodal stimulation of the DLPFC precedes working memory tasks, sometimes only reaction times improve (Mulquiney et al., 2011; Teo et al., 2011), whereas accuracy improves with concurrent anodal stimulation of the same area (Ohn et al., 2008). Moreover, the type of current waveform (e.g., direct, randomized, or regularly alternating current) may also determine whether stimulation should

precede or coincide with a task (Pirulli et al., 2013). Such mechanisms may also determine the appropriate duration of stimulation. Longer stimulation periods do not necessarily add to the effects; with longer periods, effects may fluctuate (Kwon et al., 2011). Attending to and possibly exploiting homeostatic mechanisms will be instrumental in the design of effective interventions that use repeated stimulation (Fricke et al., 2011; Ohn et al., 2008; Reis et al., 2009).

Through similar mechanisms, the behavior in which tDCS recipients engage during stimulation can also moderate response. Even a single application of a specific waveform for a given duration can dramatically alter how neural tissue responds to other inputs. For instance, low-frequency stimulation of mouse motor cortex, which typically produces LTD, instead produced LTP when done in conjunction with anodal tDCS (Fritsch et al., 2010). In human motor cortex, short-lasting voluntary muscle contraction (which is not neuromodulatory by itself) in conjunction with tDCS applied at M1 reduced or reversed the typical neuromodulatory effects of both anodal and cathodal tDCS (Thirugnanasambandam et al., 2011).

Throughout a task, however, the relevant processing and neuroplastic parameters may not be uniform. Consequently, the effects of tDCS might vary over different phases of learning. Interestingly, concurrent cathodal stimulation of V1 during a visual discrimination task was recently found to be crucial for overnight consolidation (Peters et al., 2013). In a more cognitive domain, improved planning ability as measured by a Tower of London task required cathodal stimulation of the DLPFC during acquisition and early consolidation that was also followed in later sessions by anodal stimulation. These "training-phase-specific effects" (Dockery et al., 2009) were still present a year later. Since task-specific factors likely determine the time course of homeostatic plasticity, efforts to classify and standardize them may lend invaluable insights into how and when tDCS can be optimally deployed to produce robust and lasting effects.

3. Current application through focused arrays, possibly informed by modeling of anticipated current flows (Bikson et al., 2012), or even by direct *in vivo* measurements of current flow via MRI (R. Sadlier, personal communication, April 2013), might increase the anatomic specificity of tDCS.
4. There is growing concern about blinding in tDCS experiments. Subjects given 2 mA anodal stimulation were able to identify 'active' stimulation 72% of the time and 'sham' 56% of the time during their first session. After a second session, they identified both active and sham correctly more than 88% of the time (O'Connell et al., 2012). A large group of subjects reported more tingling, itching, burning, pain, and difficulty concentrating after 1.5 mA of active stimulation compared to sham, and they reported that tingling, itching, and burning persisted longer after active than sham stimulation (Kessler et al., 2012). Although blinding by sham procedures has been considered effective at 1 mA (Gandiga et al., 2006), recent reports suggest that subjects experience more discomfort during active than sham stimulation even at 1.0 mA (Ambrus et al., 2012). In the same study, investigators (i.e., experienced tDCS recipients) were able to reliably distinguish 1.0 mA active from sham stimulation. Thus, tDCS researchers will have to either develop more effective sham stimulation procedures, or circumvent the problem by altering cutaneous perceptions. Topical anesthetics have been shown to reduce cutaneous sensations associated with tDCS at 2 mA (McFadden et al., 2010) and at high current densities (Bikson and Datta, 2012; Borckardt et al., 2012). Alternatively, sensations associated with sham stimulation could be intensified by increasing the salinity of the solution in which the sponges are soaked (Dundas et al., 2007; Minhas et al., 2011). Of course, reporting side effects of stimulation might be less important than whether tDCS recipients can distinguish between active and sham stimulation. In this respect, it is as yet unclear whether conscious or unconscious awareness of the difference between active and sham stimulation will alter the impact of tDCS in any appreciable way.
5. Experimenters have not been blinded in most studies reported to date. With the introduction of preprogrammable or remotely controllable stimulators, experimenter blinding will become a feasible standard, as long as precautions are taken to blind the experimenter to redness at the electrode site that is more apparent after active stimulation than sham (Ambrus et al., 2010; Boggio et al., 2008). Acetylsalicylic acid or skin cream can be applied immediately after taking off the electrodes to obscure this difference (Palm et al., 2013), or such masking agents could be applied by a third party, or the subject could wear a head covering.
6. Statistical designs used for tDCS studies will have to address variability within and across subjects. Traditionally, randomized block and matched-pair designs have attempted to minimize between-subject variability by blocking or matching subjects based on what are thought to be the most influential sources of variance (e.g., age, gender, education level). However, accounting for individual variability is more difficult in tDCS experiments, because individual differences in tDCS response may be larger than the variability of within-subjects measurements. So tDCS studies are often best suited to within-subjects designs, such as cross-over, factorial, and Latin square designs. Such designs also require fewer subjects than parallel designs (Chow et al., 2008; Hills and Armitage, 1979; Jones and Kenward, 2003; Senn, 1999). Cross-over designs have, in fact, been the most frequent form used in tDCS studies to date.

In cross-over designs, each subject receives the same treatments over a series of sessions, but the treatment sequence varies across subjects. Cross-over designs introduce a problem in making direct treatment comparisons because of practice effects, session effects, and carry-over effects. Counterbalancing stimulation sequences and allowing sufficient wash-out periods between sessions can minimize possible carry-over effects. Some investigators have tried to minimize practice effects by giving subjects practice before the critical experimental tasks (Ohn et al., 2008). It may be important to have participants practice tasks well before stimulation in order to avoid homeostatic effects. Experimenters have also used different but comparable stimuli for different sessions (Cattaneo et al., 2011).

There is little research about the duration of cognitive effects to inform decision-making regarding wash-out periods. The duration of alterations in motor-evoked potentials following tDCS of the motor cortex provide coarse guidelines, with effects of 20 min of anodal stimulation at 2.0 mA having

lasted for at least 120 min (Alonzo et al., 2012). Similar findings have been discovered when visual-evoked potentials were measured after stimulation of the occipital cortex (Accornero et al., 2007; Antal and Paulus, 2008), although the duration of effects was somewhat different. Wash-out periods for such observable effects seem to be the minimum basic requirements to minimize carry-over. Perhaps a better guideline would be at least 24 h after a single session of stimulation. But so little is known about the persistence of effects of repeated stimulation that it would be premature to speculate on what intervals will prove to be appropriate wash-out periods.

In short, despite taking measures to minimize period, carry-over, and possible interactions, these effects need to be considered and reported in statistical analyses. There are several choices of statistical methods that can be used in the analysis. For the simple two-treatment, two-period, cross-over trial, Hills and Armitage (1979) proposed a series of two sample *t*-tests to test the significance of direct treatment difference and period or session differences. The disadvantage of this method is that the previous effects can only be tested if the carry-over effects of the two treatments are the same.

The other choices of analysis methods include repeated measures Analysis of Variance (ANOVA) and mixed models. Jones and Kenward (2003) give a very basic statistical model for cross-over trials. In this model, subject effects can be considered as either fixed or random. The majority of reported studies have treated subjects as fixed effects or carried out analyses using two-way repeated measures Analysis of Variance (ANOVA). However, there are reasons to consider subjects as random effects (drawn randomly from a population). Furthermore, in circumstances where the subject totals contain relevant information, then these can only be recovered if the subject effects are treated as random (Jones and Kenward, 2003). In this case, mixed models should be used; See (Putt and Chinchilli, 1999) and (Brown and Prescott, 2006).

The limiting assumptions of statistical analyses are also critical for analyzing tDCS studies (as they are in general). *T*-tests assume normal distributions. The assumption of normality of data, as is assumed in *t*-tests, is usually overlooked or not reported in findings. Mixed models and repeated measures ANOVA are robust to small deviations from normality. But when statistical examination of model residuals (e.g., the Shapiro–Wilk test and visual inspection of q–q plots) reveals significant deviations from normality, then nonparametric methods must be used.

7. We join in the recent observations that many reports in the literature have been inadequately documented (Raising Standards, 2013). In fact, one finding of this article is that it was often difficult to understand exactly what the investigators did and what they actually found. In reporting tDCS experiments, it will be critical to include all relevant or possibly relevant details of the experimental situation. Description of the stimulation parameters must include the current strength and waveform, current density, total dose of current, total number of active sessions, 10–20 electrode positioning, electrode treatments including solution salinity and topical treatments, and a complete description of sham stimulation including waveform and methods to verify blinding of both subjects and assessors. Description of subjects' activities before and during stimulation is essential, as is specification as to whether data were collected during (online) or after (off-line) stimulation. Including frequently omitted information, such as the number and nature of dropouts from the study, is also important.

Finally, when reporting findings, it will be important to include effect sizes, in terms such as Cohen's d or partial eta squared (Cohen, 1988). These data will give readers a better understanding of the effectiveness of tDCS as an intervention, and they allow for possible meta-analyses. In studies with small samples (e.g., 10–20 participants), presenting profile plots of the participants or corresponding mean plots would also provide readers with a better understanding of the responses to tDCS at subject level. In larger studies, attempts to characterize responders can inform future investigations.

In this regard, we also urge experimenters to submit negative results for consideration for publication, and we urge editors and reviewers to weigh negative results as much as they do putatively positive ones.

Looking forward, increasing the range, rigor, and integration of both experimental and computational approaches to tDCS can be expected to yield rich dividends, as efforts to apply it to the understanding, enhancement, and restoration of language and cognition mature.

Acknowledgments

Preparation of this article was aided in part by the Therapeutic Cognitive Neuroscience Professorship (BG); the Therapeutic Cognitive Neuroscience Fund (BG); the Benjamin and Adith Miller Family Endowment on Aging, Alzheimer's, and Autism (BG); the William and Mary Ann Wockenfuss Research Fund Endowment (BG); and by NICHD grant HD053312 (DJS). We thank all those who have been involved in our tDCS efforts, including Drs. Elizabeth Lacey, Kerry Ledoux, Rosalind Sadleir, Richard Skolasky, Kyongje Sung, and Jacqueline R. Weaver, and Megan A. Andrejczuk, Laura V. Bosley, Patrick Chambers, Mariya Chernenok, Julia Hernandez, Kara Reese, and Mark Varvaris. James Livengood and Dr. Rasika Jayatillake are no longer with The Johns Hopkins University.

Transference in Psychoanalysis: Classical, Contemporary, and Cultural Contexts

This article is a revision of the previous edition article by R.S. Wallerstein, volume 23, pp. 15851–15856, © 2001, Elsevier Ltd.

Abstract

Transference and countertransference constitute foundational principles in psychoanalytic and psychodynamic thoughts. Freud first conceptualized transference as the patient 'transferring,' onto the analyst, reactions to major figures from early life, primarily parents. This was initially seen as an obstacle to the therapeutic work of recovering repressed pathogenic experiences of childhood into consciousness. Subsequently, Freud understood transference as essential, since it represented the reliving of repressed early experiences in the present moment and rendered such experiences accessible to interpretation. Neurotic symptomatology expressed in transference is known as transference neurosis. Psychotic symptomatology expressed in transference is known as transference psychosis. The clinician's display of neurotic transference onto the patient is known as countertransference. As with transference, countertransference was originally seen by Freud as an obstacle, but it is now regarded as an avenue to understanding the types of pressures exerted by the patient onto the analyst and an opportunity to better understand the patient. Newer traditions in psychoanalytic and psychodynamic thoughts have moved beyond models of transference and countertransference as psychic phenomena projected by individuals to consider their co-construction and cultural contexts.

Definition

Transference and countertransference constitute foundational principles in psychoanalytic and psychodynamic thoughts. Transference is the conception that our past experiences endure within us and play a formative role in our present interpersonal behaviors. In accord with his original conception that neurotic symptoms and behaviors represented earlier mental conflicts that patients had been impelled to repress from conscious memory, Freud devised the method of 'free association,' requiring the patient to verbalize every thought as it arose. This verbalization was to occur without attention to usual considerations of logical and tactful expression, i.e., no matter how seemingly nonsensical, offensive, or embarrassing. To his dismay, he found that despite the patient's conscious intent, the process of sequential narration would occasionally be blocked as the patient lapsed into shameful silence or claimed that nothing came to mind. When pressed, the patient could often acknowledge that unwanted thoughts or feelings about the analyst had come to mind, displacing the historical recounting.

Freud initially saw this as an unwelcome impediment to the joint therapeutic task of uncovering original traumatic events and tried to disengage the patient from such distractions. However, he realized the regularity of this occurrence, that it was not accidental or inadvertent, but a regular 'transferring' onto the analyst of reactions to early major figures in the patient's life, primarily parents and other significant figures from the past. In Freud's words, "They (transferences) are new editions or facsimiles of the impulses and phantasies which are aroused and made conscious during the progress of the analysis; but they have this peculiarity … that they replace some earlier person by the person of the physician. To put it another way: a whole series of psychological experiences are revived, not as belonging to the past, but as applying to the person of the physician at the present moment" (Freud, 1905/1953).

To state it simply: a feeling of anger toward the analyst, perceived in the moment as an overbearing and arbitrary authority, would be a representation of childhood interactions with the patient's father, experienced often in that light. Consequently, Freud designated transference reactions as father or mother transferences (or sibling, or mentor, or whomever), and as positive or negative transferences, depending on their emotional valences.

Freud thus reversed his reaction to transference manifestations, from seeing them as impediments to viewing them as essential. By 'analyzing' the transferences, i.e., unraveling their meanings during analysis, and tracing them as past representations of pathogenic interpersonal interactions relevant in the present, the patient's repressed traumas would be brought to light. This uncovered, their formative role in the maintenance of neurotic behaviors, would be progressively dissipated. For example, a patient's chronically damaging interactions with a work superior, perceived as arbitrary, overbearing, and impeding job satisfaction, would be progressively eased, and even eliminated as the patient interpreted them as unwitting reenactments of earlier experiences with his father.

In fact, Freud believed that because of the emotional intensity experienced in the transference interaction, compared to the remoteness of describing historical interactions in the distant past, the patient was most susceptible to analyzing the emotional impact in order to disrupt established, automatized behavioral patterns, leading to insight and therapeutic change. This effect is described in one of Freud's most famous sentences as, "For when all is said and done, it is impossible to destroy anyone *in absentia* or *in effigie*" (Freud, 1912/1958). In a well-known paper by Strachey, one of Freud's early adherents, interpretation of the transference was described as the only truly 'mutative' interpretation, all other interpretive efforts only leading up to, and supportive of, interpretation in and of the transference (Strachey, 1934). Freud's technical advice from the start was to allow analytic transferences to unfold gradually, as they inevitably would, and only to interpret them when they

crystallized in therapy as resistances to ongoing work. Such resistances could manifest either as negative transferences of hateful feelings directed at the analyst or as erotized positive transferences of loving feelings. Freud made an exception for what he called "unobjectionable positive transferences," the benign feelings that led the patient to best cooperate with the analyst, experienced by the patient as expert, helpful, and interested in effecting therapeutic change and cure. In modern times, some analysts have separated this so-called 'unobjectionable positive transference' as 'therapeutic alliance' (Zetzel, 1956) or the 'working alliance' (Greenson, 1965). Other analytic authors have, however, doubts about this unobjectionable transference, seeing it as a defensive cover that hides other objectionable transference manifestation, which would ultimately need to be interpretively undone to complete therapy.

As transference unfolded over the course of therapy, Freud further conceived of what he called the 'regressive transference neurosis' in which the presenting neurotic symptoms and behaviors stopped in patients' outer and inner lives though neurotic components came to full expression in therapy. To Freud, a fully evolved transference neurosis, focused completely on the analyst, recapitulated what he called the 'infantile neurosis,' the set of maladaptive interactions in childhood that established the template for later neurotic illness that brought the patient to treatment. The interpretive resolution of this full-fledged regressive transference neurosis marked, for Freud and many of his followers, the central task of treatment. Treatment was only successful when the transference neurosis was fully resolved and various transference distortions were transformed into an objectively realistic relationship of the patient with the therapist.

Transference Psychosis

A related concept to transference neurosis developed in the 1950s known as transference psychosis. This concept developed along two distinct trajectories. In one trajectory, transference psychosis was an analogue to the concept of transference neurosis; just as neurotic patients display 'neurotic' transference reactions to the analyst, culminating in the full-fledged transference neurosis, so also do psychotic patients display 'psychotic' transference reactions, which can coalesce into a fully formed transference psychosis. In another conceptual trajectory, a neurotic patient, seemingly well-suited for a classical psychoanalytic treatment, could develop a psychotic transference response with loss of reality testing that maintains transference as an 'as-if' phenomenon (Wallerstein, 1967).

Understanding of Transference at the End of the Twentieth Century

Since Freud's time, our understanding of transference has been transformed significantly. For example, Gill and Hoffman (1982) squarely challenged the notion that transference manifestations consist only of the projections of the patient's past relationship patterns upon the neutral objective analyst who would be the sole arbiter of reality. Given the inherent ambiguity in all human relationships, Gill saw transference as the patient's plausible construction of his or her experience of the analyst and of the analytic interaction. Analytic work would then be understood as the co-construction of how the patient and analysis each differently perceive the same interaction, each perception being the product of the individual life experience of the perceiver, with individually different predispositions toward preferred ways of endowing meaning to the encounter. Therapeutic focus would be on the psychology of the patient, what life experience disposed him or her to construe the therapeutic interaction in the manner manifested, and to link the lived past to the present transference manifestations. The past is still present in the transference as an underlying template of interpersonal expectations, but focus has shifted to a present-day interaction in the here-and-now of the therapeutic encounter as immediately experienced by the two participants. In other words, focus has shifted from the discovery of the past emergent in the present to the interaction in the present as framed by the past.

Along with that has been the concomitant shift from transference as a purely intrapsychic phenomenon within the patient, projected onto the neutral, objective, and uninvolved analyst (what is now called one-person psychology), to transference as an interaction of two subjectivities, each bringing their own built-in predispositions to that interaction. The focus remains the patient's construal of the situation, embedded in the life experience and consequent neurotic structuring of the patient. This is now called two-person psychology, the intersubjective interaction of two participants, though focused on the difficulties of the patient. These altered conceptions of the transference have been developed further within the object-relational perspective in psychoanalysis as distinct from Freud's perspective, called now drive/structural, or put differently, two-person versus one-person psychologies (Stolorow et al., 1978 or Greenberg and Mitchell, 1983). Finally, Neil Altman (1995) has contended that culture and society appear within the therapeutic dyad in what is termed as the third-person model. In this formulation, the significance of racial, cultural, and socioeconomic class differences of the patient and analyst are analyzed as providing the content of the transference.

Analytical Techniques

These modern interpretations in ideas of transference have led to alterations in analytical technique. The focus is now on the early interpretation of transference and on seeking out implicit allusions to the transference to render them explicit. The idea of unfolding full-fledged transference neurosis as a necessary recapitulation of the infantile neurotic experience has yielded to a variety of transference manifestations in the present in unique relationship patterns, with past and present relationship experiences in constant dialectical interplay.

This entire history of transference development has been summarized in an article by Cooper (1987), in which he contrasted 'historical' and 'modernist' models of transference. In Cooper's words, "The first idea, close to Freud, is that the transference is an enactment of an earlier relationship, and the task of transference interpretation is to gain insight into

the ways that the early infantile relationships are distorting and disturbing the relationship to the analyst, a relationship which is, in turn, a model for the patient's life relationships. I shall refer to this as the *historical* model of transference, implying both that it is older and that it is based on an idea of the centrality of history. The second view regards the transference as a new experience rather than as an enactment of an old one. The purpose of transference interpretation is to bring to consciousness all aspects of this new experience including its colorings from the past. I shall refer to this as the *modernist* model of the transference, implying both that it is newer, in fact still at an early stage of evolution, and that it is based on an idea of the immediacy of experience." In the historical concept, transference is an intrapsychic phenomenon of one person, the patient; and in the modernist concept, it is an interpersonal phenomenon, involving two people.

Analysts working within three-person models have also contributed to techniques that uncover the cultural and social bases of transference. Using Altman's (1995) conception of transference as the co-constructed relationship between the patient and analyst based on race, culture, and social status, Aggarwal (2011, 2012) has contended that transference and countertransference can be seen as a 'cultural third,' in which cultural values, meanings, and expectations must be analyzed to understand what is at stake for the patient during analytic work. This perspective recognizes that patient and analyst must find a way to bridge social and cultural differences embedded in their separate life experiences to negotiate a way toward therapeutic work. One way of uncovering the cultural sources of the patient's transference reaction is to use the Cultural Formulation Interview published in Diagnostic and Statistical Manual of Mental Disorders (DSM-5) that includes questions to the patient on how his or her cultural identity relates to their presenting problems and their expectations of care from the analyst (American Psychiatric Association, 2013).

Countertransference

The counterpoint to transference is known as countertransference. Originally, countertransference was conceived by Freud as the analyst's inappropriate and nonobjective responses to the patient's transferences, stemming from unresolved issues that were elicited by the patient's transferences. This would cloud the analyst's proper evaluation of transference. Countertransference, therefore, paralleled Freud's original view of transference as an impediment to analytic work. In this conception, the remedy was constant watchfulness by the analyst, to monitor inadvertent and inappropriate responses, and to control facial expression and prevent contaminating transference display. If such monitoring proved ineffective, an additional remedy would be rigorous self-analysis or the need for the analyst to return to his or her own therapy. This view later came to be called the 'narrow' conception of the countertransference. Others, especially those working with sicker patients, widened the conception of countertransference as the totality of the analyst's emotional responses to the patient; this would include countertransference, all emotional reactions by the analyst to the patient as a whole, and to the activity of analysis itself. This wider conception was called 'totalistic,' and some analysts (Winnicott, 1949) divided countertransference into 'neurotic' and 'objective' components.

Though Freud came to understand transference as essential to therapeutic work, he failed to take the same step in considering countertransference. Only in the early 1950s did psychoanalysts, first in the UK, begin to view countertransference not as an occasionally inadvertent and inappropriate intrusion upon therapeutic work, but as inevitable and as a constant expression of the analyst's involvement with the patient in interactive treatment. This moment reflected a shift to the totalistic conception of the countertransference as the entirety of the analyst's emotional responses to the patient, whether in specific reaction to the patient's transferences, or whether as stemming from the analyst's developmental history and overall responses to the patient and to therapy between them.

In this time, it was further theorized that through careful monitoring of countertransference thoughts and feelings, the analyst could obtain useful insights into what the patient was trying to get the analyst to think or feel. These insights would lead to a wider knowledge of the patient's psychological and developmental history. This process of arousing emotional responses within the analyst has been variously called 'projective identification' (by the Kleinian school of psychoanalysis) or 'role responsiveness' (by the classical Freudian school; cf Sandler, 1976). In this conception, the perception of countertransference has likewise shifted from an initial view of an occasional and inappropriate intrusion upon therapy (to be overcome by the analyst), to an inevitable and necessary vehicle toward understanding the patient. The conceptual evolution of countertransference has therefore mirrored the conceptual evolution of transference. In the same way that content of transference has also been seen to be inherently cultural (Altman, 1995; Aggarwal, 2011), countertransference has also been shown to emerge in relation to similarities and differences in race, culture, and ethnicity with the patient that can yield essential insights into underlying psychic conflicts (Comas-Díaz and Jacobsen, 1991).

Therefore, transference and countertransference are completely equivalent, neither being just a response to the other, but each stemming from the psychological development of the respective parties to the therapeutic process. Some analysts (cf McLaughlin, 1981) have therefore even called for the elimination of the word countertransference, calling both sides of the interaction as transference and without privileging either.

Countertransference evocations tend to be more subtle and contained among psychologically mature analyst, and with classically typical neurotic patients. These evocations become more severe and difficult to contain with sicker patients, typically narcissistic or borderline in their character organization and seen with increasing frequency in psychoanalytic and psychotherapeutic practices. The intense transference–countertransference interplay results in what are often called 'role enactments' such that the analyst feels impelled to take on the role (punitive authority, benign rescuer, neglectful parent, etc.) that the patient, through conscious or unconscious speech and behavior, elicits from the analyst. By

interpreting situations in which the analyst inadvertently adopted or fell into the assigned role, the analyst can become aware of his or her countertransference involvement and use this to clarify psychic pressures from the patient. When identified, these pressures become insights into the patient's character predispositions and can be traced to the patient's developmental history.

A major issue, and a matter of professional controversy, is when the analyst can communicate to the patient's aspects of understanding countertransference. There are some who utilize countertransference as additional avenues of understanding the patient and would avoid any countertransference 'confession' to the patient to prevent self-disclosure or to spare the patient from an additional psychic load to bear. Others advocate for analysts to share their countertransference responses with the patient under certain circumstances as ways of obtaining an understanding of what kind of reaction the patient wanted to evoke in the analyst, how this reaction reflects relationships outside of therapy, and the kinds of responses that are elicited among others. There are other instances where the patient detects the countertransference response before the analyst is aware of it ("You are angry at me and taking it out on me"), and the analyst should deal with these instances truthfully and tactfully rather than to deny or avoid it.

A final point about transference and countertransference: Therapy is a highly contrived arena in which emotional reactions are elicited in an intimate and intensely meaningful that can be subjected to mutual scrutiny. Such scrutiny can enhance psychological understanding of neurotic issues (and their developmental history) in a patient seeking relief from mental and emotional difficulties. But it should be evident by now that we all live by transferences in all of our relationships. We always bring ourselves, our personalities and characters, as shaped and colored by our pasts, into our interpersonal encounters, and we see our present relationships and expectations largely through dispositions cultivated by past experiences. In fact, it can be said that our entire capacity for relationships, for empathy with others, even for creative endeavor in any arena, rests on the transferences that we bring and live by (cf Loewald, 1980).

Summary

All of the issues covered in this article are summarized in Aggarwal (2011), which explains conceptions of transference and countertransference in one-, two-, and three-person models of psychology, with subsequent recommendations for clinical practice.

Abstract

Gender identity refers to an individual's experience or identity in relation to gender. Transgender, transsexual, and gender variant individuals (often considered under the umbrella term of transgender or trans*) have gender identities that are not congruent with the gender assigned to them at birth. Trans* identity and experiences are framed with regard to medical perspectives, social and legal perspectives, and community perspectives.

Gender identity refers to an individual's experience or identity in relation to gender. For transgender, transsexual, and gender variant individuals, gender identity is not congruent with the gender assigned at birth. In contrast, *cisgender* is a term that refers to individuals whose gender identity is congruent with the gender assigned at birth. Although the experiences of transgender, transsexual, and gender variant individuals may be distinct, they are often considered under a common umbrella term of *transgender* or *trans**. Individuals who fall under the trans* umbrella may include cross-dressers, transvestites, transsexuals, drag kings and queens, as well as individuals who identify as transwomen, transmen, bigender, two-spirit, androgynous, genderqueer, gender nonconforming, and gender variant.

Medical Perspectives

Current understandings of gender identity have been greatly impacted by the pervasive medical framework that has sought to define trans* experience. Although there is great variation in how trans* individuals relate to gender identity terminology, the term transsexual has been particularly impacted by its use in a medical context. The psychiatric literature in particular distinguishes between transvestites and transsexuals. *Transvestism* is characterized by a focus on clothing of the opposite gender. In contrast, the focus for *transsexualism* is on gender identity, where an individual's gender identity is not congruent with the gender assigned at birth. Thus, the medical literature focuses on individuals who transition (or are in the processing of transitioning) their bodies to better match their gender identity. Medical perspectives on trans* experience are focused on providing treatment, often in the form of *gender reassignment surgery* (GRS) or other gender affirming treatments inclusive of hormone therapy, surgical alteration of secondary sex characteristics, or otherwise altering physical appearance or presentation to better match the target gender.

The focus on medical transition of transsexual individuals creates a focus on the body (specifically the genitals) that obscures the fact that many trans* individuals do not seek medical transition (Grant et al., 2011; Bockting, 2014). For example, for many gender nonconforming trans* individuals, there may be no transition process at all. Alternatively, transition may describe their journey from the gender they were assigned at birth to their current gender identity (which may or may not be male or female). Trans* individuals may not medically transition for various reasons. Some trans* individuals do not feel that their body needs to be altered in order to socially transition while some trans* individuals do not see their bodies as incongruent with their gender identity. Many other trans* individuals do not medically transition because they do not have access to the financial resources, insurance, or social support network necessary to facilitate such a transition. In addition, while some individuals view their trans* experience as an important part of their identity, others view their trans* experience as a status or a medical history. There is great variability with regard to disclosure as not every individual who is trans* feels the need or desire to disclosure their trans* identity or status (Zimman, 2009).

Diagnostic Categories: Gender Identity Disorder and Gender Dysphoria

The formal diagnoses and treatment of trans* individuals in the medical establishment came in 1980 with the dual emergence of diagnostic categories of Gender identity disorder (GID) and the establishment of the Standards of Care (SOC) for the Health of Transsexual, Transgender, and Gender Nonconforming People. GID is conceptualized as the experience of significant discontent with the sex assigned at birth and/or with the gender roles associated with that sex. Formal diagnoses of GID became possible with the publication of the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders III (DSM-III) in 1980 and its associated inclusion in the International Classification of Diseases (ICD-10).

Initial diagnoses of GID rely heavily upon an individual's cross-sex identification, rejection of sex-'appropriate' behavior, and dissatisfaction with the body. With the 2013 reclassification of GID to gender dysphoria in the DSM-5, modifications were made to address earlier criticisms. In particular, diagnostic criteria for gender dysphoria focuses less on gender identity, and instead centers on the experience of distress. This allows for an end point for the diagnoses. In addition, diagnostic criterion in the DSM-5 shifts the language from sex to gender in order to encompass individuals who are intersex (have biological characteristics at birth of both males and female) and those whose have gender nonconforming trans* identities.

Standards of Care

The World Professional Association for Transgender Health, Inc. (WPATH), formerly the Harry Benjamin International Gender Dysphoria Association, Inc., is a professional organization devoted to the understanding and treatment of gender dysphoria. Originally founded in 1979, the organization was named after Dr Harry Benjamin, one of the first physicians in the United States to begin work with transsexuals. In 2007, the organization changed its name to WPATH. WPATH is best known for publishing the SOC for the Health of Transsexual, Transgender, and Gender Nonconforming People. Prior to the publication of the SOC there was no medical consensus for procedures or approaches in providing safe, legal medical options for trans* individuals. The SOC, first drafted in 1979 has been periodically revised (1980, 1981, 1990, 1998, 2001, and 2011). The SOC established a process and timeline of therapy before medical treatment for trans* individuals. The original SOC recommended that prior to GRS trans* individuals should obtain recommendations ('letters') from at least two psychologists/psychiatrists, should be established on hormonal treatment for at least 6 months, and have lived exclusively in the role of the chosen gender for at least a year. In addition, these guidelines suggested that a 'good candidate' for GRS included having a lack of sexual activity and no history of prostitution.

There are a number of criticisms of the medical establishment's framing of trans* experience. Through the diagnostic categories and the SOC, trans* individuals' gender identity and presentation is scrutinized and regulated by medical professionals. In addition, trans* individuals are placed in a position to 'prove' their gender identity in order to receive treatment (Serano, 2007; Stryker, 2008). Medical providers, then, often serve as 'gatekeepers' to medical and gender affirming treatments. Some trans* individuals advocate for the declassification of gender dysphoria as a psychiatric category and criticize the way in which the medical establishment pathologizes trans* individuals and reinforces false notions of sex and gender as binary. In addition, the prior classification of GID under Sexual Dysfunctions and Paraphilic Disorders in the DSM has been scrutinized as contributing to the conflation of sexual orientation and gender identity.

The current change from GID to gender dysphoria in the DSM-5 and the publication of the most recent version of the SOC signals a shift toward providing comprehensive trans* care that is more inclusive of gender nonconforming identities and nonmedically transitioning trans* identities (Coleman et al., 2012). These changes reflect the larger shift within the medical and psychological communities to expand trans* care and research. Although these changes are significant, the authority of the medical community to define trans* bodies and identities continues to serve to pathologize experience within larger society.

Social and Legal Perspectives

Despite greater medical and social recognition of trans* identities, individuals who are (or are perceived as) trans* continue to face discrimination, harassment, and bias-motivated violence in many areas of their lives due to the irrational fear and/or hatred and negative cultural ideology embedded in *transphobia*. Violent behavior and hostility is estimated to be four times higher for trans* individuals when compared with the national average; 26% of respondents in the National Transgender Discrimination Survey (Grant et al., 2011) reported having been physically assaulted on at least one occasion because of anti-trans bias. Trans* women (transition from male to female) are disproportionately affected, with half of lethal anti-lesbian, gay, bisexual (LGB), and transgender hate crimes committed against trans* women and girls. At the same time, 50% of transgender people report they are uncomfortable seeking police assistance (Grant et al., 2011).

This negative climate fosters hate crimes against trans* people and contributes to their 'invisibility.' In a society invested in gender dimorphism, the emotional expression of *genderism* (the ideology that there are, and should be, only two genders that are inevitably tied to the gender assigned at birth) and the violent manifestation of these emotions occurs through discriminatory behavior in the form of *gender bashing*. *Such gender bashing* perpetuates the ways that gender operates as a vector of regulation and distribution, describing a coercive system that orders the world through gender-based violence (Beemyn and Rankin, 2011).

In addition to high rates of violence and imprisonment, trans* individuals' experience severe economic insecurity and exclusion from social services. They are more likely to experience hostile or aggressive familial interaction, more likely to be kicked out of their homes by parents, more likely to become homeless or live below the poverty line, and are less likely to be employed. Ninety-seven percent of trans* individuals reported having experienced some form of workplace harassment or discrimination on the basis of gender identity or expression, with more than one in four trans* adults having lost at least one job due to bias (Grant et al., 2011). Trans* people of color, trans* youth, trans* people with disabilities, homeless, and undocumented trans* populations are particularly vulnerable. These compounding factors have resulted in limited health care access, familial aid, and other resources, further increasing the risk of harassment, discrimination, and violence.

Legal Recognition and Protection

There has been no broad law or legal strategy that offers full protection for members of the trans* community, but rather protections have been made in a more piecemeal approach that has left trans* individuals legally vulnerable. Historically both disability protections and sex discrimination laws have been utilized in select cases involving gender identity, although there has been criticism by the medical community that marking transgenderism as a disability only further stigmatizes the population, while still specifically excluding gender variant individuals who do not fit the Americans with Disabilities Act guidelines (ACLU, 2013). Regarding the limitations of law reform as intervention, trans* scholar, Dean Spade (2011) explains that a key challenge facing trans* politics is how to properly account for the uneven distribution of vulnerability and violence across trans* populations due to varying levels of vulnerability within the community at large. Policy language is a vital detail in providing protections. Each policy must be

broad enough to cover all the variation within the population but specific enough to provide actual protection. Currently, the framework of studying, describing, and addressing the discrimination faced by trans* persons through the single vector of transphobia often causes the erasure of the reality of conditions facing those most vulnerable, such as trans* people of color or gender variant individuals (Spade, 2011).

Advocates of trans* equality have primarily pursued two law reform interventions: antidiscrimination laws that list gender identity as a category of nondiscrimination, and hate crime laws that include crimes motivated by the gender identity of the victim as triggering the application of a jurisdiction's hate crime statute. In 2009, the *Matthew Shepard and James Byrd, Jr.* Hate Crimes Prevention Act became the first and only federal hate crime law to include gender identity; however, at the time of this writing, there was still legislative debate regarding the inclusion of gender identity in the Employment Non-Discrimination Act (Transgender Law and Policy Institute, 2013). The passage of federal antidiscrimination laws would create a nation-wide basis for legal claims against discriminating employers, housing providers, restaurants, hotels, stores, and the like. Despite 13 states and 108 counties/cities having such laws, the National Gay and Lesbian Task Force (2009) analysis of jurisdictions with explicitly trans*-inclusive nondiscrimination laws posits that only 39% of the population is actually protected.

Gender identity is the most common phrase used for policies or laws that protect trans* rights, conceivably for its power of immutability (GenderPAC, 2007). Most nondiscrimination laws do not explicitly include gender identity, but prohibit discrimination based on perceived, as well as actual, sexual orientation, limiting a trans* individual's protection to the perpetrator's belief (accurate or not) that the victim was gay. While trans*-inclusive nondiscrimination laws can offer legal protections based on gender identity/expression, sexual orientation, sex, disability, and citizenship, accurate and up-to-date documentation like necessary identity documents (i.e., driver's license, passport) and records (i.e., birth certificate, social security) is usually a prerequisite for access to education, jobs, community services, and safe spaces (ACLU, 2013). According the National Survey (2009), only one-fifth of trans* individuals are actually able to update all of their legal credentials to match their current gender identity.

Trans* Case Law

Although federal laws banning sex discrimination (Title VII of the 1964 Civil Rights Act; CRA) do not prohibit gender identity discrimination, federal courts that have considered the issue more recently have found some protections in the CRA for trans*-specific cases (ACLU, 2013). The landmark case of *Smith v. City of Salem* held that a trans* firefighter suspended from his job after complaints that his appearance was not 'masculine enough' had an actionable claim for sex stereotyping based on his gender nonconforming conduct and his gender identity. Smith's original allegation that his suspension was 'based on sex' was dismissed at both the state and federal levels, ruling that Title VII prohibition of sex discrimination does not include gender identity (TL and PI, 2013). In his appeal, Smith relied on the US Supreme Court's decision in *Price Waterhouse v. Hopkins* regarding a woman's 'overly masculine' dress/appearance to support his claim that discrimination based on sex stereotyping warrants Title VII protection, successfully drawing an analogy with Smith's claim to the *Price Waterhouse* claim based on sex stereotyping (TL and PI, 2013).

Future of Trans* Rights

Even with the increasing number of states adopting more inclusive antidiscrimination laws, including the legal recognition of same-sex marriage, the legality of these contracts relies on the definable and legally recognized sex. Additional current trans* discrimination topics being addressed at the grassroots level include trans* participation in collegiate and professional sports, trans* protections in the military, the use of public spaces like homeless shelters and gender-specific resource centers, gendered prison assignment, adoption/child custody rights, among others. However, legislation has yet to officially tackle many of these issues, because the failure to cohesively articulate oppression and discrimination results in the inability to claim retribution, since one must be able to name the act of harm/exclusion in order to seek legal justice (Lair, 2013). While all these topics are considerably important to the growth of trans* inclusion and recognition, determining the most pressing issues is contingent upon which intersection is being challenged within and outside of the trans* community.

Community Perspectives

Creating a Modern Transgender Movement

Until the introduction of a conscious 'transgender politic' in the 1990s, trans* communities in the United States historically organized around issues rather than shared identity.

'Transvestite' groups from the 1950s, for example, catered exclusively to heterosexual cross-dressing males by supporting homophobic and antitranssexual policies. These early communities did not see themselves as marginalized. In fact, they sought acceptance for the clothes that they wore – attempting to expand dress norms for 'proper' men – rather than for the act of cross-dressing itself. Isolating these experiences from a deeper examination of self, participation in these groups provided the opportunity to explore gender expression without threatening one's reputation (Stryker, 2008). From elite cross-dressing groups to lobbyists on Capitol Hill, there has never been a single transgender community with a cohesive set of goals. The transgender movement has developed its contemporary structure, rather, as particular communities address their needs within changing political climates.

While issue-based advocacy in the 1950s had little to do with identity, the 1960s saw coalitions of marginalized people organizing around shared discrimination. In the 1969 Stonewall Riots, often considered the origin of the 'homophile' or gay rights movement, transgender women joined with drag queens ('transvestites'), gay men, and lesbians in a violent reaction to routine police harassment. Three years earlier, economically segregated transgender women in the Tenderloin District of San Francisco rioted at Compton's Cafeteria. They

allied themselves with communities of color to protest harmful urban land-use and domestic war policies (Stryker, 2008). Although these riots did not create immediate structural change, they succeeded in altering broader perceptions of transgender citizenship. Through the shared political interests underlying these protests, transgender communities – such as 'Vanguard,' a street organization for gay and trans* youth in Tenderloin (an historically economically depressed neighborhood in San Francisco) – began to take shape.

These emerging transgender communities, however, complicated the identity politics characteristic of the homophile and feminist movements in the 1970s and 1980s and there was tension among these different movements from the outset. The homophile movement's assimilationist strategies were particularly vulnerable to transphobia through the act of 'gender baiting,' by which LGB activists sought to differentiate themselves from more subversive gender presentations among transgender individuals (Feinberg, 1996). Likewise, transgender identities challenged feminist ideology based on a monolithic womanhood set apart from anything masculine. Transgender women were explicitly excluded from the yearly Michigan Womyn's Festival and subject to belligerently transphobic rhetoric from many feminist scholars. Facing antagonism from all ranges of the political spectrum, transgender communities through the 1980s tended to be small and locally funded (Stryker, 2008). In New York, Stonewall veterans Sylvia Rivera and Marsha P. Johnson founded Street Transvestite Action Revolutionaries, while the Queens' Liberation Front organized political demonstrations and the popular publication *Drag*.

Transgender subgroups individually developed their own political identities, not converging in a structured fashion until the 1990s. Unlike male-to-female (trans* women) communities, who had been openly identified and active for the past two decades, transgender men only began to organize in the 1970s. Historians attribute this time lapse to female-to-males' ability to present themselves more convincingly as young men, therefore not needing to ban together for mutual support in the same way as transgender women (Stryker, 2008). The line between transgender friendships and organizations are not always clear, however, meaning that many communities serve both social and political functions. Just as each transgender population has its own political goals, these communities also serve different social functions. They can be characterized generally as networks that provide shared experiences, tools to reduce social stigma, and information lacking within traditional resources (Hines, 2007).

Uniting disparate communities under the political identity 'transgender' and merging – at least in name – with LGB activists, the contemporary transgender movement surfaced in the 1990s. The first indication that local, issue-based advocacy would give way to a national network of organizations was the acquired immunodeficiency syndrome (AIDS) crisis. Responding to AIDS brought together a wide coalition of communities affected by the disease, as well as offering financial resources to transgender individuals who were seen as particularly vulnerable to contracting the human immunodeficiency virus. AIDS activism relied on 'queer politics,' which gave birth to the academic discipline of Queer Theory. Queer, a reclaimed slur that embodies any challenge to traditionally oppressive sexual and gender norms, provided the language and tools for transgender communities to articulate their own political interests. Although transgender issues were marginalized in the Queer Nation movement, activists formed a suborganization called Transgender Nation that pressured LGB groups to promote transgender inclusion. Queer theory created new language to discuss gender, helping to spark a movement of nonbinary trans* identities (Stryker, 2008), and the arrival of the Internet was a means to connect transgender voices and experiences from across the country (Beemyn and Rankin, 2011).

Trans* Identity Politics

Individual trans* activists and communities' political goals correspond profoundly with how they draw the boundaries of 'transgender' (Davidson, 2007); in other words, the process of deciding who belongs under the trans* umbrella further implies whose interests are being advocated. The question of defining trans* identity politics owes its roots to the history of inclusion and exclusion within broader LGB and feminist movements. One school of thought promotes a borderless trans* community that avoids issues of hierarchy that have plagued other social movements, perpetuating inequalities among subgroups. Feminists, for instance, clashed over who could legitimately identify as women and therefore 'deserved' access to movement resources – often marginalizing transwomen, lesbians, women of color, and working-class women (Serano, 2007). Kate Bornstein introduces the equalizing concept of 'gender outlaws' who violate the rules of gender, implying that there is an essential fluidity that characterizes trans* identities (1994). Julia Serano, however, sharply critiques this 'antiidentity movement' that ignores the lived differences between various populations. She prefers to imagine transgender as a "set of alliances rather than monolithic communities" (2007: p. 142). The umbrella model of trans* identity can fail to express the ideological and political tensions between subcommunities who may disagree as to who belongs within the broader coalition.

A great point of controversy between transsexual and gender variant communities, for example, is the degree to which abolishing the gender binary is seen as a fundamentally transgender issue. Routine academic critiques of sex and gender from both feminist and queer theorists have been described as undermining transsexual identities, just as the political movement to remove gender dysphoria from the DSM often ignores the medical and legal realities of physical transition (Davidson, 2007: p. 68). Despite the architecture of umbrella politics, several hierarchies have emerged that reflect ideological boundary drawing. There are tropes that stereotype transsexuals as 'assimilationists' for typically presenting themselves within the binary. Such 'subversivism' can rank those who present as gender variant as somehow superior to more traditional presentations (Serano, 2007). On the other hand, genderqueer and nonbinary communities are often assumed to be white, young, educated, and socioeconomically privileged.

Boundary drawing reflects power inequalities in that more powerful subgroups are able to set political agendas that either include or exclude particular populations. Intersex communities are often included under the trans* umbrella, usually without consultation, which in itself reveals power disparities. Because intersex bodies disrupt the sex binary between male

and female, activists describe this co-optation as "trans people using intersex to validate [their own identities]" (Davidson, 2007). A more implicit type of boundary drawing occurs when individuals adopt 'mainstreaming' or assimilatory politics with the goal of their transgender identity/status no longer being an issue. Most sociologists agree that it is easiest for those with social privilege to reject identity as an organizing principle (Davidson, 2007). In other words, those who want to mainstream transgender experiences are not people who also experience racism, classism, or other forms of inequality. By not seeing how trans*-related discrimination intersects with these systems of inequality, privileged trans* folks promote a political agenda that does not address the oppression of less privileged individuals.

Debate over the role of cisgender allies in the modern trans* movement can also reflect power inequalities. Leslie Feinberg's strategy for allyship – the recognition that "each individual has a stake in trans liberation" (1996: p. 92) – does not always account for cisgender privilege. Transgender rights articulated within a broader gender rights movement often invoke unequal power dynamics, due to the fact that critical examinations of 'gender' usually address binary identities while marginalizing trans* experiences. When GenderPAC, famous for popularizing genderqueer identities, changed its mission in 2000, activists observed how this reduced the work GenderPAC did in trans* communities (Davidson, 2007). When cisgender and trans* individuals face different political realities, failure to recognize privilege perpetuates inequalities.

Julia Serano's vision of allyship more explicitly addresses issues of privilege between trans* subpopulations and cisgender allies. She pivots away from Feinberg's strategy by advocating for a trans* movement that would allow boundaries to grow naturally but focuses primarily on building alliances among various communities (2007). This vision of trans* identity politics acknowledges the intersection between gender rights and transgender issues. It also implies that effective allyship must include the mutual recognition of our distinct privileges and lived experiences. While we each have a stake in issues such as employment, housing, violence, and health care, allyship recognizes that these individual issues affect each trans* subpopulation and cisgender allies differently. Contemporary organizations such as the National Center for Transgender Equality and the National Transgender Advocacy Coalition are structured as coalitions, representing the trans* movement as Serano suggests: "a set of alliances rather than monolithic communities." This ideological return to issue-based politics draws the boundaries of transgender identity quite extensively while also respecting the importance of individualized identity.

Transient Epileptic Amnesia

Serge Hoefeijzers, University of Edinburgh, Edinburgh, UK
Adam Zeman, University of Exeter Medical School, Exeter, UK

Abstract

Transient epileptic amnesia (TEA) is characterized by brief, recurrent episodes of transient amnesia occurring as a result of epilepsy. During these episodes, declarative memory is impaired while other cognitive functions remain intact. TEA is a syndrome of mesial temporal lobe epilepsy (TLE), which typically affects middle-aged people, particularly men. The amnesic attacks often occur on waking and can be accompanied by other symptoms of TLE such as automatisms, olfactory hallucinations, and short periods of unresponsiveness. EEG may reveal interictal epileptiform activity arising from the temporal lobes. Gross structural abnormalities are rarely observed, but group studies reveal subtle volume loss in hippocampal, perirhinal, and orbitofrontal cortices. The amnesic seizures respond very well to anticonvulsant medication, though most patients (around 80%) report interictal memory problems such as accelerated long-term forgetting (ALF), autobiographical, and topographical memory loss. These often persist despite successful treatment of the epilepsy. ALF, which is reported by around 50% of patients with TEA, involves the rapid forgetting of newly acquired information, occurs within 24 h of acquisition, and is likely to reflect a deficit in early memory consolidation or subtle impairments in memory acquisition. The autobiographical memory loss, seen in around two-thirds of patients with TEA, appears to be due to a degradation of established memories, though impairments of acquisition, consolidation, and retrieval may also play a part. These interictal memory difficulties are likely to result from either subtle structural damage in the medial temporal lobes or physiological disruption of memory processing by subclinical epileptiform activity.

Introduction

Transient epileptic amnesia (TEA, a term coined by Kapur, 1990) is a form of temporal lobe epilepsy (TLE) characterized by recurrent episodes of transient amnesia. During these episodes, the sufferer is unable to form new memories (anterograde amnesia) and/or unable to retrieve established memories (retrograde amnesia). These brief (usually less than 1 h) attacks of amnesia occur in middle-aged or elderly people and are sometimes the sole manifestation of epilepsy (in around one of three cases). Besides these ictal features, TEA is associated with two striking forms of persistent interictal memory impairment, namely accelerated long-term forgetting (ALF) and remote memory deficits (especially affecting autobiographical and topographical memory). ALF is the accelerated loss of newly acquired information that usually takes place over subsequent days to weeks (Butler et al., 2007; Zeman and Butler, 2010). This chapter discusses the background of the syndrome of TEA and reviews the ictal and interictal features of this unusual form of epilepsy of which the main manifestation is amnesia.

Clinical Features and Demography

TEA typically begins in late-middle to old age (mean age at onset is around 60 years) and is predominantly found among men (male:female ratio is 2:1) (Butler et al., 2007). The amnesic episodes usually occur around once a month. The exact number of attacks is likely to be higher as episodes sometimes go unnoticed (if the patient has no recollection of them and the attack occurs unwitnessed).

Amnesia is the sole manifestation of TEA in around one-third of patients. In other cases, the amnesic event is associated with other more familiar manifestations of epilepsy like olfactory hallucinations, automatisms such as lip smacking and chewing, or a brief period of unresponsiveness. Patients occasionally report other types of seizure, usually complex partial seizures, in which amnesia is not the most prominent feature. Tonic–clonic seizures occur rarely. Attacks often occur upon waking (around 70% have at least some of their attacks on waking) and typically last 30 min to 1 h, though, shorter (several minutes) and longer (several hours) episodes also occur. During the attack, 50% of patients ask repetitive questions such as 'Where am I?,' 'What day is it?' These questions reflect both an element of retrograde amnesia (patients are unable to access information laid down shortly before the episode which would allow them to orient themselves) and an element of anterograde amnesia, as they are often unable to remember the answers given to their questions. Anterograde amnesia is often partial: after the attack, in 44% of the cases, patients 'remember not being able to remember.' Apart from amnesia, cognitive functioning remains largely or wholly intact (Butler et al., 2007; Zeman and Butler, 2010).

The medial temporal lobes (MTLs) are likely to be the seizure source. Indeed, bilateral seizure activity in the temporal lobes is the most common ictal EEG-abnormality (detected in 8 out of 10 cases monitored during an attack). Interictal epileptiform abnormalities (where present) have been observed both bilaterally (56%) and unilaterally (32% left-sided, 12% right-sided) (Butler and Zeman, 2008b). Major structural abnormalities are rarely detected. However, mild bilateral hippocampal, perirhinal, and orbitofrontal atrophy has been detected in TEA patients as a group in two recent studies (Butler et al., 2009, 2013).

The amnesic episodes of TEA respond very well to anticonvulsant medication, with cessation of attacks on a modest dose of a single anticonvulsant drug in almost all cases. Despite this

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51067-8

clear-cut response to low doses of antiepileptic drugs (AEDs), most patients (around 80%) report interictal memory problems that persist to some degree after successful treatment of the attacks: 70% report a patchy loss of remote memories of salient autobiographical events such as weddings or holidays (i.e., autobiographical amnesia); 44% of the patients complain that newly acquired information fades abnormally rapidly from memory over days to weeks: this phenomenon is referred to as ALF. Moreover, 36% have difficulties in finding their way around areas they used to be very familiar with (i.e., topographical amnesia) (Butler et al., 2007; Zeman and Butler, 2010). These persistent interictal memory impairments are discussed in more detail further below.

The characteristics of the syndrome (sudden and late onset) and nature of the ictal and interictal memory complaints sometimes make patients concerned that they are in the early stages of dementia. However, despite raising understandable doubts in patients' minds about their memory performance, TEA does not elevate levels of anxiety or depression markedly (Butler and Zeman, 2008b).

Diagnostic Criteria for TEA and Differential Diagnosis from Other Transient Amnesic Syndromes

Episodes of transient amnesia, in which the patient experiences an acute onset of dense memory loss, are striking clinical events that present a diagnostic challenge to the physician. TEA is by no means the only cause for such episodes: they can be induced by disorders including transient global amnesia (TGA), head injuries, transient ischemic attacks, drug intoxication (e.g., alcohol, benzodiazepines), migraine, hypoglycemia, psychogenic fugue, and electroconvulsive therapy (Bartsch and Butler, 2013). In TEA, acute amnesia is, in one-third of cases, the sole 'visible' manifestation of the seizure. Not surprisingly, TEA can be misdiagnosed for other syndromes of transient amnesia – it is most often confused with TGA, transient ischemic amnesia (TIA) due to a transient ischemic attack or minor stroke, and psychogenic amnesia. Dementia is sometimes suggested as a possible cause, although it has not, in fact, been established that dementia presents in this way. The distinctive features of the four main causes of transient amnesia are summarized in **Table 1**.

TGA gives rise to a dense anterograde and more variable retrograde amnesia lasting for several hours, often provoked by physical exertion or psychological stress, most often occurring on only a single occasion. TIA typically manifests itself in combination with additional neurological symptoms or signs suggestive of dysfunction of the posterior cerebral circulation and is often accompanied by somnolence. Psychogenic amnesia is often distinguished by the presence of a psychiatric history, psychiatric precipitants, and profound retrograde memory loss, sometimes including loss of personal identity, in the presence of normal anterograde memory.

The diagnostic criteria for TEA itself (Zeman et al., 1998) are

- A history of recurrent, witnessed episodes of transient amnesia.
- Other cognitive functions besides memory, judged by a reliable witness, are intact during typical episodes.
- Evidence for a diagnosis of epilepsy based on one or more of the following:
  - epileptiform abnormalities on EEG,
  - concurrent onset of other clinical features of epilepsy (such as lip smacking or olfactory hallucinations),
  - clear-cut response to anticonvulsant therapy.

The diagnosis of TEA is primarily clinical. An epileptiform EEG supports the diagnosis, but as in other forms of epilepsy a single routine EEG is a relatively insensitive test (positive in around one of three cases) and a normal EEG does not, therefore, exclude a diagnosis of epilepsy. Sleep deprivation can be used to increase the sensitivity of EEG. EEG is expected to give essentially normal results in TGA, TIA, and psychogenic amnesia.

MRI will generally be normal in TEA, but may reveal evidence of cerebrovascular disease in TIA. Diffusion-weighted imaging will often show punctate changes in the hippocampi 48–72 h after an episode of TGA (Bartsch and Butler, 2013).

Living with TEA: Treatment and Prognosis

Treatment

Treatment of TEA is often delayed owing to misdiagnosis of patients as having TGA, TIA, psychogenic attacks, or dementia (Ioannidis et al., 2011; Bartsch and Butler, 2013). As a consequence, patients with TEA typically experience several episodes of amnesia before the correct diagnosis is established. AEDs have been found to be extremely effective at stopping the seizures. A low dose of a single anticonvulsant drug is usually sufficient (Butler et al., 2007). Effective AEDs in TEA include lamotrigine, levetiracetam, carbamazepine, and sodium valproate.

Prognosis

In contrast to dementia, TEA does not appear to cause a progressive decline in memory, although this has not yet been studied formally. Anticonvulsant medication usually prevents the occurrence of further amnesic attacks. Although patients sometimes report a subjective improvement in memory generally when anticonvulsant treatment is started, it has not been formally established that the persistent memory problems associated with TEA (including ALF, autobiographical amnesia, or topographical amnesia) improve on treatment with AEDs (Bartsch and Butler, 2013). This issue is discussed further below. Despite the persistent memory problems caused by TEA, patients generally maintain an active, independent life. Driving may be restricted for a period following diagnosis.

TEA: Case Histories

As mentioned earlier, TEA is characterized by the frequent occurrence of relatively short episodes of amnesia as a result of TLE. During these attacks, anterograde and/or retrograde memory are impaired while other cognitive functions remain intact. We provide two typical examples of TEA, before outlining what is known of the pathology and pathophysiology.

Table 1 Key diagnostic features of transient epileptic amnesia (TEA), transient global amnesia (TGA), transient ischemic amnesia (TIA), and functional/psychogenic amnesia

	TEA	*TGA*	*TIA*	*Functional*
Typical age	50 + years	50 + years	50 + years	Any age
Duration	Typically <1 h	Typically 4–6 h	Variable,<24 h	Typically days or months
Acute memory deficits	Variable mix of anterograde and retrograde amnesia – may later remember attack	Dense anterograde amnesia; variable retrograde amnesia	Not well characterized	Variable, but often dense retrograde amnesia (+/− loss of personal identity) with preserved anterograde memory
Other features (sometimes present)	Olfactory hallucinations, automatisms, brief loss of awareness	Headache, nausea	Focal neurological symptoms and signs, usually arising from posterior circulation	Other functional symptoms and signs may be present; mood disturbance
Precipitants	Waking	Physical (esp. immersion in cold water) and psychological stresses	–	Stressful life events, minor head injury, mood disturbance
Recurrence	Once a month on average	6–10% Recurrence rate/year	Recognized but not well characterized	Unusual but occurs in, e.g., recurrent psychogenic fugue
Medical history	No established risk factors	Migraine	Cerebrovascular risk factors	Psychiatric illness, 'organic' transient amnesia, substance abuse
Interictal/postictal memory	+/− Mild impairment on standard tests; accelerated long-term forgetting, remote memory loss, topographical amnesia	Subtle subclinical impairment may persist for days–months, but no permanent deficit	Risk of lasting memory impairment from completed stroke	Variable

Case 1

L.S., a 62-year-old retired woman, experienced nine episodes of amnesia, until successful treatment with levetiracetam. About half of the amnesic episodes occurred on awakening and some were accompanied by olfactory hallucinations (a 'burning' smell) or unresponsiveness with tongue biting. The episodes of amnesia generally lasted around 20 min to half an hour and were occasionally accompanied by repetitive questioning. According to her husband, she communicated normally during these episodes and, besides the evident memory problems (anterograde and retrograde amnesia), other cognitive abilities remained intact. He described a particular occasion where they had gone to buy bread together. While paying for the bread, she abruptly wandered out of the shop and entered an amnesic state until arriving back home about 15 min later. She 'remembered not being able to remember' in several of the episodes, suggesting that her anterograde amnesia was incomplete. Moreover, on some occasions, memory loss for past events (retrograde amnesia) had been dramatic. For example, in the very first attack, she did not remember that her son and his girlfriend were staying at her home. Around the time that her seizures began, she noticed a deterioration in her memory for familiar places and routes, and a tendency for memories for events to fade more rapidly than she would expect.

Case 2

Mr. B.K. experienced his first amnesic attack at the age of 67 while living in Cyprus. The episode of amnesia came on at the end of a morning spent chopping logs on a hot day. When his wife first noticed something was wrong, he initially failed to recognize her, and then asked questions such as 'What am I doing here?,' 'Where are we?' His cognitive functioning appeared otherwise normal. The amnesic state persisted for about 90 min, and then gradually recovered. He was taken to hospital where he was told initially that he had suffered a stroke. However, on returning to England, he was told that the episode was likely to be one of TGA. Mr. B.K. then began to have briefer episodes of amnesia, often, but not always, occurring on waking. If they occurred on waking, he would ask such questions as "Where are we?," "What day is it?" His amnesic state would gradually improve over about 30 min. These episodes were preceded by nonspecific warnings of 'funny feelings in the head.' Over the year, 12–15 attacks occurred before diagnosis of TEA was established. Moreover, amnesic episodes of a different kind were also witnessed. These short episodes, lasting only for several minutes, were accompanied by lip smacking and humming. Recovery was rapid and memory was not affected by these attacks. During a 24-h ambulatory EEG, nonspecific slow wave activity was observed over the anterior temporal lobes (more marked on the left side), together with rare sharp waves over the left temporal lobe indicating a liability to a partial onset seizure disorder. In conjunction with his seizures, he noticed a tendency for memories to fade more rapidly than he would expect.

Not all cases of TEA are as clear cut as the ones described. The amnesic episodes described in both cases are typical for TEA. Attacks on waking provide a valuable diagnostic clue, but do not always occur. Features such as olfactory hallucinations

or automatisms, suggesting epilepsy, can be absent. As in other focal epilepsies, the interictal EEG may be normal and structural imaging is typically normal. However, brief, recurrent amnesic attacks, especially when combined with interictal complaints of autobiographical, topographical, and/or anterograde memory loss are strongly suggestive of TEA (Butler and Zeman, 2008b; Zeman and Butler, 2010). The diagnostic criteria for TEA mentioned earlier provide a useful summary of key diagnostic features, though as with most such criteria some patients who suffer from the disorder will fail to satisfy them.

Biology of TEA

Several lines of evidence indicate that TEA is a medial TLE. These include clinical features such as the prominence of amnesia in attacks of TEA, the high frequency of olfactory hallucinations, and the associated oroalimentary automatisms (Zeman and Butler, 2010). Structural abnormalities, though rare, and epileptiform discharges, when present, point to the temporal lobes (Butler and Zeman, 2008a, 2008b; Zeman et al., 2013). Recent studies have identified subtle, bilateral hippocampal atrophy across the whole patient group (~8% volume decrease compared with controls) (Butler et al., 2009) with additional bilateral atrophy in the perirhinal and orbitofrontal cortices.

The Microscopic Neuropathology

While there is little information about the neuropathology of TEA, postmortem investigations in a patient with TLE who showed ALF, together with autobiographical memory loss, yielded evidence of neuronal loss and gliosis in regions of both the right and the left hippocampus. The neuronal loss and gliosis were more evident in anterior than posterior hippocampus (Butler et al., 2012).

The Underlying Cause

It is unclear why TEA should mainly occur later in life. Further research on clarifying the relationship between TEA and other forms of late-onset TLE might shed more light on this issue. Suggested explanations include underlying cerebrovascular disease, a neurodegenerative disorder, and a form of immune-mediated limbic encephalitis. These options could explain the age distribution, though at present, there is no compelling support for any of these possibilities (Zeman et al., 2013): no evidence is found for increased risk or burden of vascular disease in TEA (Butler and Zeman, 2011) and an underlying neurodegenerative or immune-mediated disorder is also not observed in the great majority of cases (Razavi et al., 2010).

Accelerated Long-Term Forgetting

Even once the amnesic attacks have been successfully treated with low doses of antiepileptic medication, a substantial number of TEA patients (44%) report difficulty in retrieving memories from the recent past (from around a day to a few weeks before) despite apparently normal initial memory (Butler and Zeman, 2008b). This phenomenon of accelerated forgetting is not unique to TEA and has also been described in patients with other forms of TLE (Blake et al., 2000; Kapur et al., 1997; Kemp et al., 2012; Lucchelli and Spinnler, 1998; Martin et al., 1991; Mayes et al., 2003; O'Connor et al., 1997; for an exception, see Giovagnoli et al., 1995).

Despite often complaining of memory impairment for day-to-day events, TEA patients usually perform normally – that is, within one standard deviation of the mean – on memory tests at standard retention intervals (~30 min) (Butler et al., 2009). This might be taken to suggest that the patients' subjective long-term memory complaints are not in fact the result of a memory disorder at all, but instead, for example, are related to mood disorders (Corcoran and Thompson, 1993). Recent research, however, found no evidence of severe mood changes in TEA: anxiety and depression scores were normal (Butler and Zeman, 2008b). Moreover, tests designed to examine memory at longer intervals have objectively demonstrated an abnormal decrement in long-term memory performance. This phenomenon of accelerated forgetting, occurring over hours, days, or weeks, despite normal retention at the standard 30-min delay interval, provides an alternative explanation for the patients' subjective memory complaints. Indeed, scores on subjective memory measures in TEA correlate with objective measures of ALF but not with standard memory measures (Butler et al., 2009; Zeman et al., 2013). Memory tests with extended retention intervals are likely to be a valuable addition to the neuropsychologists' tool kit in patients with epilepsy (Witt et al., 2012).

The Clinical and Neuropsychological Features of ALF

Experimental tasks using extended retention intervals have revealed increased forgetting rates over intervals varying from 24 h to 6 weeks for verbal and nonverbal laboratory material (Butler et al., 2007, 2009; Manes et al., 2005) and real-life events (Muhlert et al., 2010). When ALF first becomes apparent is not yet known. However, recent studies in patients with TEA and TLE have found that ALF becomes apparent within the first 24 h after learning (see **Figure 1**; for word lists and real-life events: Muhlert et al., 2010; for stories: Jansari et al., 2010 for word pairs: McGibbon and Jansari, 2013).

Undoubtedly, the timescale of ALF, measured under laboratory settings, depend on the test material used (e.g., word lists, stories, word pairing, designs, real-life events) and the experimental protocol applied (e.g., number of learning trials or exposure times, frequency of recall and recall interval) (Butler et al., 2007; Jansari et al., 2010; Kemp et al., 2012; Manes et al., 2005; McGibbon and Jansari, 2013; Muhlert et al., 2010). For example, spaced retrieval of material can prevent or reduce the occurrence of ALF (Jansari et al., 2010; McGibbon and Jansari, 2013) while repetition of immediate retrieval during word list learning does not appear to be effective (Hoefeijzers et al., 2013).

The impact of anticonvulsant medication on long-term forgetting is still an unresolved issue. Many TEA patients show ALF despite effective control of the amnesic episodes by

Figure 1 Mean recall performance of TEA and control groups on the list learning test at the last trial and after delays of 40 s, 30 min, 1 day, 1 week, and 3 weeks. TEA = All patients with TEA; Good Learners = TEA patients who were good learners (only those meeting the learning criterion). Error bars show 95% confidence intervals. Reprinted from, Muhlert, N., Milton, F., Butler, C., Kapur, N., Zeman, A. Accelerated forgetting of real-life events in Transient Epileptic Amnesia. Neuropsychologia 48 (11), 3235–3244, © 2010, with permission from Elsevier.

antiepileptic medication (Butler et al., 2007; Manes et al., 2005; Muhlert et al., 2010), indicating that ALF is not typically prevented by such treatment. Pre- and post-treatment studies on ALF show contradictory results: no substantial changes in long-term forgetting were observed in a TEA patient after 6 months of AED treatment (Jansari et al., 2010), while AED treatment did prevent accelerated forgetting in other patients (Midorikawa and Kawamura, 2007; O'Connor et al., 1997). There is, at present, no clear explanation for these conflicting results, but it could be that in some patients ALF is due to subclinical epileptiform discharges, which may be sensitive to anticonvulsant treatment, while in others structural factors, which are not sensitive to treatment, are responsible. This question is discussed further in the next section.

The Biology of ALF

The pathology underlying ALF remains unclear. Given that (1) to date the phenomenon has been reported almost exclusively in association with epilepsy (though see Manes et al., 2005 for an exception) but (2) ALF remains observable, despite abolition of seizures by AEDs, it has been proposed that clinical and subclinical seizure activity may both play a causative role in ALF (Zeman and Butler, 2010). Indeed, several studies have found a correlation between seizure frequency and long-term forgetting rates in epilepsy (Fitzgerald et al., 2013; Mameniskiene et al., 2006; Tramoni et al., 2011; but see Blake et al., 2000 for an exception). Moreover, some studies report improvement of long-term memory performance with treatment of seizures (Gallassi et al., 2011; Midorikawa and Kawamura, 2007). Alternatively, given the persistence of ALF in many patients despite abolition of seizures, ALF could be related to structural brain abnormalities (Zeman and Butler, 2010). Narayanan et al. (2012) observed that the presence or absence of hippocampal damage in TLE determined whether patients showed ALF. However, among patients with TEA, no relationship was found between long-term forgetting rates and regional brain volumes (Butler et al., 2009).

The Cognitive Architecture of ALF

The underlying cognitive basis of ALF also remains uncertain. The pattern of relatively intact retention over short delays, coupled with poor retention after longer delays is suggestive of a deficit in memory consolidation (Blake et al., 2000; Butler et al., 2007; Hoefeijzers et al., 2013; Muhlert et al., 2010). There is evidence for ALF at 24 h in TEA (Muhlert et al., 2010). In TLE, a single case report indicates that it can be detected within 1 h (McGibbon and Jansari, 2013). While it has been suggested that ALF might result from impairment of memory consolidation during sleep, a preliminary study indicates that the benefit of sleep for memory is preserved in patients with TLE (Deak et al., 2011). An impairment of a relatively early stage of memory consolidation is thus a strong candidate for the cognitive basis of ALF, and it may be that the precise timing of the impairment varies between patients. Nevertheless, a subtle impairment of memory encoding, weakening the memories at the time of acquisition, without affecting memory retrieval at the standard test interval of 30 min, remains a possible explanation (Hoefeijzers et al., 2013; Kopelman, 2000; Muhlert et al., 2010).

Remote Memory Impairment

Remote memory impairment, especially affecting autobiographical and topographical memory, is another persistent interictal memory deficit frequently observed in TEA (Butler et al., 2007; Zeman and Butler, 2010). Seventy percent of patients with TEA report remote loss of memory for salient autobiographical events such as weddings or holidays (i.e., autobiographical amnesia). Patients are usually able to remember that the events took place and they had

participated in them. They are, however, unable to re-experience these autobiographical memories vividly and cannot remember details of the events. Moreover, 36% of patients with TEA complain of having difficulties in finding their way around areas they used to be very familiar with (i.e., topographical amnesia) (Butler et al., 2007; Zeman and Butler, 2010). These complaints of topographical memory loss in TEA have, however, not yet been quantified in detail. As in the case of ALF, similar remote memory problems have been described in patients with other types of TLE (Addis et al., 2007; Butler and Zeman, 2008b; Noulhiane et al., 2007; St-Laurent et al., 2009, 2011; Viskontas et al., 2000).

The Clinical Features of Remote Memory Impairment

In keeping with patients' subjective autobiographical memory complaints, Butler et al. (2007) observed autobiographical memory loss across the four most recent life decades in 22 TEA patients, using a modified version of the Autobiographical Memory Interview (AMI) (Kopelman et al., 1989). Moreover, personal semantic memory was also slightly impaired over the most recent decades. Similar results were observed by Manes et al. (2005) using the Galton–Crovitz test of cued autobiographical memory. Here, seven TEA patients showed autobiographical memories loss for events that happened two decades earlier (period of 1985–94) but not for autobiographical memories of the five most recent years (period 1995–99). More recently, Milton et al. (2010) tested 14 TEA patients and 11 age- and IQ-matched controls using the Autobiographical Interview (Levine et al., 2002). In contrast to the results of Butler et al. (2007), autobiographical memory loss was observed across the entire lifespan (see **Figure 2**) and was present for all the different types of contextual information (event, time, place, perceptual, and thought/emotion details). This test difference may well be due to the use of the Autobiographical Interview, which is thought to be more sensitive than the AMI (Zeman et al., 2013). Again these patients showed mild impairments of personal semantic memory and, to a lesser extent, of public semantic memory (Milton et al., 2010).

The inability to retrieve autobiographical memories acquired many years before the onset of TEA, in the absence of any deficit on standard tests of anterograde memory, indicates that TEA is a form of focal retrograde amnesia as this term is usually understood (Butler et al., 2007; Manes et al., 2001, 2005; Milton et al., 2010; Zeman et al., 2013). Notably, the patients' subjective memory complaints correlate with performance on remote autobiographical memory tests, but not with standard test of anterograde memory (Butler et al., 2009). Therefore, this remote memory deficit seems to be, just like ALF, a nonstandard form of memory impairment that contributes to the patient's everyday memory complaints, while not being detected on standard memory tests (Zeman et al., 2012).

The Biology of Remote Memory Impairment

Unlike standard anterograde memory test results, measures of autobiographical amnesia and ALF are not related to focal atrophy in the temporal lobes (Butler et al., 2009) and orbitofrontal regions (Butler et al., 2013). These two unusual forms of selective long-term memory loss have no gross anatomical correlate. It is more likely that subtle structural damage or physiological disruption, presumably by subclinical epileptic activity, affect the function and connectivity of memory networks to cause these two forms of epilepsy-related long-term amnesia (Butler et al., 2012; Milton et al., 2010). Indeed, Milton et al. (2012) found that during retrieval of autobiographical memories, activation of the autobiographical memory network was less extensive in TEA patients than in control participants. Hypoactivation was detected particularly in regions of the right hemisphere: activation was reduced in the posterior parahippocampal gyrus (pPHG) (especially for mid-life and recent memories), the temporoparietal junction, and the cerebellum. Moreover, the connectivity between the right pPHG and right middle temporal gyrus was also diminished.

The Cognitive Architecture of Remote Memory Impairment

TEA patients can lose the ability to vividly re-experience autobiographical memories acquired many years before the onset of TEA. Whether this remote memory loss reflects a deficit in memory acquisition, consolidation or retrieval is still not known with certainty, but the available evidence suggests that a degradation of existing engrams plays an important role (Dudai, 2004).

A subtle anterograde memory deficit seems unlikely to explain this remote memory impairment. First, in many cases, there is strong evidence that the lost autobiographical memories had previously been accessible over long periods of time. Second, despite the late onset of the epilepsy and its associated memory complaints, the autobiographical memory loss affects the entire lifespan. While a subtle anterograde memory deficit such as ALF would be expected to give rise to loss of episodic memories acquired after the onset of TEA, it is unlikely to explain the lifelong depletion of autobiographical memory loss seen in patients with TEA (Zeman et al., 2012).

Failure to maintain stored memories provides the best explanation for the autobiographical memory loss seen in TEA (Tramoni et al., 2011). This could reflect damage to stored engrams or, relatedly, a deficit in very long-term consolidation processes or reconsolidation mechanisms (Dudai, 2006; Wang and Morris, 2010).

A retrieval deficit could also hinder the retrieval of remote memories. However, it is unlikely to be the main cause for the autobiographical memory loss seen in TEA. First, it would be expected to complicate the retrieval of very recently acquired memories as well, but these often appear to be spared in patients with TEA. Second, extensive cueing, both verbally and visually, fails to improve recollection of autobiographical memories (Manes et al., 2001, 2005; Muhlert et al., 2010; Milton et al., 2010). However, Milton et al. (2011) report a single TEA patient who recovered some 'lost' autobiographical memories following a series of episodes of *déjà vu*, suggesting that indeed some autobiographical memory 'loss' might be due to impairments in memory retrieval (Zeman et al., 2012).

Figure 2 Mean number of details recalled for events from five life periods by patients with TEA compared with control participants. Reproduced from Adam Zeman, Chris Butler, Nils Muhlert, and Fraser Milton. Novel forms of forgetting in temporal lobe epilepsy. Epilepsy & Behavior 26, 335–342, © 2013, Elsevier with permission.

Autobiographical Memory Loss in TEA and Theoretical Models of Memory

There are currently two principle theories of remote autobiographical memory. The 'standard' theory of consolidation proposes that autobiographical memory traces are transferred over time, via 'systems consolidation,' into neocortical locations in which they become independent of the hippocampi (e.g., Squire and Bayley, 2007). In contrast, the multiple trace theory (MTT) suggests the hippocampal complex is involved life-long in the evocation of rich autobiographical memories (e.g., Moscovitch et al., 2005; Rosenbaum et al., 2001). At first sight, the uniform impairment of autobiographical memories extending across the entire lifespan appears more in line with the predictions of MTT. However, the standard consolidation theory could explain these results if epileptiform activity spreading from the MTLs disrupted the cortical memory network. Therefore, current findings fail to adjudicate between these theories (Zeman et al., 2013).

Conclusion

TEA is a form of TLE characterized by recurrent episodes of transient amnesia caused by epilepsy. This epileptic syndrome usually occurs in middle age and is often accompanied by ALF and remote memory impairment. Both interictal complaints are nonstandard forms of memory deficits, which are at least partially resistant to AEDs and can occur in the face of normal performance on standard memory tests (Zeman et al., 2013).

Recent work has elucidated the clinical features, pathology, and pathophysiology of the transient amnesic attacks occurring in TEA, and the associated ALF and remote memory loss. Further research on the relationship between epilepsy and memory impairments in TEA will deepen our understanding of the morphological and physiological processes involved in the formation, storage, and retrieval of episodic memories. Understanding how epileptic activity disturbs these processes may allow more effective treatment of epilepsy-related memory disorders in the future (Zeman et al., 2013).

Transient Global Amnesia

Juliane Döhring, Karsten Witt, and Thorsten Bartsch, University Hospital Schleswig-Holstein, University of Kiel, Kiel, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Transient global amnesia is an acute onset amnesia characterized by an anterograde and retrograde amnesia of declarative memory lasting less than 24 h without concomitant neurological deficits. The prognosis of this enigmatic syndrome is benign. Although the exact etiology and pathogenesis remain cryptic, focal lesions confined to the CA1 field of the hippocampus can be detected in magnetic resonance imaging. These findings indicate a perturbation of hippocampal dependent memory circuits as the correlate of the amnesia. Here, we will describe the clinical presentation of transient global amnesia and illustrate associated pathogenetic mechanisms.

Introduction

Short-lasting amnesic syndromes were recognized already in the nineteenth century (Ribot, 1882; Sollier, 1892). In the classic French neurological literature of the nineteenth century, cases of transient amnesia have been reported that occurred as a consequence of an emotional event (Gil et al., 2010). Guyotat and Courjon (1956) provided the first systematic phenotypical description of the syndrome by characterizing its clinical and epidemiological properties in 17 patients. Fisher and Adams (1964) referred to this phenomenon as 'transient global amnesia' (TGA) and suggested hypotheses about its possible etiology.

Nowadays, TGA is a defined clinical syndrome that is characterized by a sudden onset of a severe amnesic syndrome that extends to all sensory modalities (therefore 'global'). An amnesic syndrome is defined by the inability to learn new, consciously accessible – or explicit – information (anterograde amnesia). This deficit is accompanied by difficulty recalling events that occurred prior to the damage (retrograde amnesia). Retrograde amnesia is often temporally graded in that remote memories, acquired well before the lesion, are better preserved than recent memories. By definition, nonmemory cognitive domains such as perception, cognition, general intelligence, and praxis are intact.

In the following, an overview of the present state of TGA research will be provided, beginning with its epidemiological properties, its anatomical underpinning, the diagnosis, and possible differential diagnosis. The majority of TGA patients report certain precipitating events before TGA onset that will be characterized in the next section. Further, the main hypotheses of TGA pathology will be presented. Finally, some findings from imaging studies will be summarized.

Clinical Presentation

The clinical presentation of TGA is temporally limited, ranging from a few hours up to (per definitionem) 24 h (Bartsch and Butler, 2013). The onset is sudden and manifests in an inability to recollect recent experiences or form new memories. The amnesia affects all modalities of senses (visual, verbal, tactile). The retention span of the anterograde deficit at its peak may last only 2–3 min. When the attention shifts, the retention span may be even shorter. Stereotype repetition of statements or repeated questioning concerning situational circumstances or objects that changed in the recent past is typical. Because of the inability to reconstruct recent events, patients are frequently confused and disorientated in time and place (Owen et al., 2007). The retrograde amnesia varies between individuals and can extend to weeks or decades into the past. Most patients cannot recollect what they had been doing at the beginning of the attack.

Apart from the amnesia, TGA patients do not show impairments of cognition, vigilance, or procedural knowledge. Their intellectual functions are preserved and they are in fact able to accomplish complex operations like driving a car, cooking, or gardening. Working memory is largely maintained as well as procedural memory, priming, conceptual, and public knowledge. During the acute state social skills, awareness of the own identity or the identity of close family members should be retained. A loss of self-awareness and consciousness excludes the diagnosis of a TGA. However, mostly patients are not explicitly aware of their memory failure. Instead they 'feel' something is not quite right without being able to name it explicitly.

Beyond amnestic symptoms, an altered emotional state can sometimes be observed: some patients exhibit a certain helplessness, perplexity, irritation, and/or anxiety or fear to die. Some patients cry and exhibit symptoms close to a panic attack (Inzitari et al., 1997). An altered emotional state and signs of depressed mood can aggravate the amnesic deficit. Deteriorations of the emotional state improve following the dynamic of the episode (Noel et al., 2008).

TGA can be accompanied by mild vegetative symptoms such as headache, vertigo, nausea, cold extremities, chills, or flushes and may be accompanied by a moderately elevated blood pressure (Quinette et al., 2006).

After a few hours, the retrograde amnesic deficit gradually resolves from remote to recent memories. Likewise, the short-term memory recovers gradually, reflected by an extending retention span. Typically after recovery an amnesic gap for the acute TGA episode remains (Sander and Sander, 2005).

Case Example

Mrs. E. is a 71-year-old biologist who had an open-heart surgery several years ago and since then, thoughts about this episode stirs up

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51064-2

her emotions. In general, she describes herself as a rather anxious person with a past history of migraine. In April she watched a medical documentary in TV, dealing with the subject 'heart surgery.' She asked her husband to switch off the TV program because she did 'not want to be confronted with it again.' Minutes after this event she repeatedly asked the same questions ("Who put the suitcase there?" "Where does the flower vase come from?"). Both objects were quite recently arranged on that place. On the way to the hospital she was alert, but her repeated questioning indicated a profound anterograde amnesia with a retention span of 2–3 min. After several hours, she fully recovered but a lack of memory covering the acute phase remained. Neurological examination, EEG, and cerebrovascular ultrasound were normal. Subsequent magnetic resonance imaging (MRI) 2 days later showed a diffusion lesion in her left hippocampus.

Diagnosis and Differential Diagnosis

Diagnosis

Diagnosis of TGA is based entirely on the clinical history and examination. Caplan (1985) proposed diagnostic criteria that were supplemented by Hodges and Warlow (1990a,b). The diagnosis of TGA relies primarily on clinical findings and comprises the criteria in Table 1. Caplan and Hodges added the exclusion of other causes of amnesia. Although not explicitly mentioned, there is a temporally graded retrograde amnesia present during the attack. Certain mild vegetative symptoms may occur additionally.

Differential Diagnosis

If the clinical symptoms do not match the diagnostic criteria (due to an ambiguous symptomatology, no reliable witness, presence of vascular risk factors), certain differential diagnoses have to be excluded (Bartsch and Deuschl, 2010) (Table 2). The first category of differential diagnosis that may rarely mimic a TGA includes (1) vascular diseases: stroke in hippocampus and thalamus (Berli et al., 2009), transient ischemic attack (TIA) in the vascular distribution of the posterior cerebral artery, infarction in the territory of the anterior choroidal artery (Bartsch and Deuschl, 2010) as well as strategic diencephalic lacunar syndromes. If stroke risk factors have been detected, an MRI and/or CT, an echocardiography, as well as a cardiac check-up are required. (2) The second category, which can mimic a TGA refers to epileptic activity including prolonged complex partial seizures or nonconvulsive status epilepticus as well as a transient epileptic amnesia (TEA) (Table 3). TEA may be difficult to differentiate from a TGA, but usually attacks are shorter (~1 h) but more frequent (~3–4 per year) and respond well to anticonvulsive medication (Berli et al., 2009). In contrast to TGA, TEA carries a risk of developing persistent memory impairment, which can be mistaken for dementia (Zeman and Butler, 2010). Epilepsy can be ascertained by means of an electroencephalogram. In young patients suffering from diabetes, hypoglycemic seizures or hypoglycemia itself can lead to TGA-like symptoms. (3) Subacute prodromal encephalitis such as herpes simplex encephalitis or limbic encephalitis can lead to an amnesic syndrome. (4) Head injuries like cerebral contusion sometimes produce posttraumatic retrograde amnesia. (5) Amnesic syndromes caused by drug intake (hypnotics, benzodiazepines, opioids, antidepressants, marijuana, alcohol) have to be excluded. Side effects of psychotropic medication such as psychiatric pharmacotherapy should be considered (Bartsch and Deuschl, 2010). Hence, a drug history should be obtained. (6) Also psychogenic syndromes might elicit TGA-like presentations: functional dysfunctions after emotionally affecting events in general as well as psychiatric disorders (e.g., dissociative episodes, psychogenic fugue, acute episode of depression). Psychogenic amnesia typically involves profound retrograde amnesia, often with loss of personal identity, in the context of preserved new learning.

Table 1 Diagnostic criteria for transient global amnesia

Diagnostic criteria for transient global amnesia after Caplan and Hodges (Caplan, 1985; Hodges and Warlow, 1990a,b):
● The presence of an anterograde amnesia, that is witnessed by an observer
● No clouding of consciousness or loss of personal identity
● Cognitive impairment limited to amnesia
● No focal neurological or epileptic signs
● No recent history of head trauma or seizures
● Resolution of symptoms within 24 h

Mild vegetative symptoms (headache, nausea, dizziness) might be present during the acute phase. Temporally graded retrograde amnesia is usually present during the acute attack, although this feature is not included in the current diagnostic criteria.

Table 2 Differential diagnostic considerations of transient global amnesia

Differential diagnostic considerations of transient global amnesia
● Vascular diseases: ischemia in the posterior cerebral circulation
● Intoxication, adverse drug side effects
● Complex focal seizures, 'transient epileptic amnesia,' postictual conditions
● Psychogenic syndromes: functional amnesia, psychogenic fugue, dissociative conditions, acute episode of depression
● Posttraumatic amnesia after head injury
● Hypoglycemia

Table 3 Diagnostic criteria of transient epileptic amnesia

Diagnostic criteria of *transient epileptic amnesia* after Zeman et al. (1998) and Butler et al. (2007)
● A history of recurrent witnessed episodes of transient amnesia
● Cognitive functions other than memory judged to be intact during typical episodes by a reliable witness
● Evidence for a diagnosis of epilepsy based on one or more of the following:
• Epileptiform abnormalities on electroencephalography
• The concurrent onset of other clinical features of epilepsy (e.g., lip-smacking, olfactory hallucinations)
• A clear-cut response to anticonvulsant therapy

Epidemiology

The incidence of TGA per year ranges between 3 and 8 per hundred thousand (Miller et al., 1987; Hodges and Warlow, 1990a,b; Berli et al., 2009). A Finnish study found a higher incidence (10 per hundred thousand per year in the general population, 32 per hundred thousand for patients older than 50 years (Koski and Marttila, 1990)). The peak of incidence is located in the 7th decade of age (mean = 60.3 years of age, based on 246 patients described in the literature (Quinette et al., 2006)). The majority of attacks (75%) occur between the age of 50 and 70 years. An occurrence in persons younger than 40 years and above 80 years is rare.

Gender Distribution

Gender seems almost uniformly distributed in TGA. In their metaanalysis, Quinette et al. (2006) did not find a significant gender difference (46.4% men, 53.6% women) among 1333 patients collected from 86 published studies. However, men and women probably differ in terms of the risk factor profile. Women more frequently report a history of migraine and tend to develop a TGA after an emotionally arousing event more often than men. Men were more frequently engaged in physical exerting activities before TGA.

Time of Onset

In the literature, an unequal seasonal distribution of TGA is reported, peaking in spring and summer (61%). In autumn and winter only 33% of the cases have been described (Quinette et al., 2006). With respect to the time of day, a TGA attack most frequently occurs in the morning (59% from 6.00 to 11.30 a.m.), the remaining part is distributed equally between afternoon and evening. There is no reported case of TGA starting in the night (between 0.00 and 6.00 a.m.) or waking up with a TGA.

Precipitating Events

The majority of patients (about a half up to 90%, depending on subjective criteria) report precipitating events that happened immediately before TGA onset. About half of these patients experienced emotional stress or physical effort preceding the attack. About a third was exposed to water contact, temperature change or acute pain, or had sexual intercourse (Figure 1).

Typical precipitating situations of the 'emotionally induced TGA' (Merriam et al., 1992) are stressful events like quarrels, the receipt of bad news, a heated argument, attending a funeral, family reunions, overwork, money worries, or reliving of traumatic situations. Quinette et al. (2006) emphasize the importance of remote factors regarding the personality profile of TGA patients. Persons with an anxious profile and phobic personality traits seem more vulnerable to develop a TGA (Figure 2).

Men are more likely to experience a TGA after physical effort like sports, housework, gardening, and arousing manual activities like coating a boat or sawing wood. Some precipitants contain both psychic and physical arousal like sexual intercourse, health problems in general, medical diagnostic procedures and acute pain. Examples for 'merely somatic' precipitants are Valsalva-associated maneuvers (e.g., coughing, emesis, straining). TGA may be elicited by sudden changes in body temperature. TGA provoked by sudden immersion in cold or hot water tends to cluster in the summer months. Some patients were particularly exposed to temperature changes (washing their hair). Rarely, changes in the atmospheric environment (at high altitudes) are reported. Caplan (1990) suggested that the main categories of precipitants (stress, effort, water) can be considered as abrupt changes in physical activity, temperature, or atmospheric environment, which may evoke an emotional, hormonal, or autonomic body response. The circumstances of TGA occurrence can be also summarized under psychic and physical stress reactions, changes of bodily homeostasis, an allostatic overload, and changes in emotional state (Merriam et al., 1992; Kessler et al., 2001).

Cognitive Outcome

Although the recovery seems complete within 24 h, it is controversially debated whether TGA results in longer-lasting, but more subtle neuropsychological deficits (Quinette et al., 2003; Bartsch et al., 2006; Jager et al., 2009a) as subtle effects persisting for several months following an acute episode has been described (Guillery-Girard et al., 2006). Kessler et al. (2001) report slight disturbances in verbal and nonverbal long-term memory as well as in verbal fluency a few days after the TGA attack. Some patients exhibit a persistent, but subclinical impairment of memory functions (Caffarra et al., 1981). However, in a metaanalysis comprising 25 studies, Jager et al. (2009a) did not identify significant differences in long-term performance between TGA patients and healthy controls. Uttner et al. (2012) did not determine significant cognitive differences between TGA patients and healthy controls in a 2-year follow up. This was aimed at patients with and without detected diffusion-weighted imaging (DWI) lesions. Also complaints concerning the emotional state (anxiety, irritability, fatigue) resolve, though in some cases they persist for some days after the episode. Neri et al. (1995) report a higher rate of mood disorders several months after the acute state.

Recurrence

In principle, TGA is considered a benign condition. The rate of recurrence varies widely across studies, depending on the length of the follow-up duration. Melo et al. (1992) reported a recurrence rate of 2.9%, whereas Fredericks (1990) registered a recurrence rate of 26.3%. In the series of Quinette et al. (2006), 3.5% of 142 TGA patients had a second episode between 1994 and 2004. Gandolfo et al. (1992) compared the survival curve of TGA patients with the analogous curve of sex- and age-matched healthy controls. The curves did not differ significantly.

Figure 1 Frequency graphs of various precipitating events preceding the onset of an acute TGA (Quinette et al., 2006). Used with permission from Oxford University Press. Modified after Bartsch and Deuschl (2010), used with permission from Elsevier.

Neuropsychology

The central neuropsychological feature of TGA is the retrograde as well as the anterograde impairment of declarative memory with the anterograde component being more profound (Eustache et al., 1999; Guillery-Girard et al., 2004). The formation of declarative memory contents is primarily based on the hippocampus and the temporal lobe system. Declarative memory comprises semantic and episodic memory. Episodic memory represents memory of personal experiences and specific events in time and space that can be explicitly stated. Semantic memory includes facts, meanings, concepts, and knowledge about the external world and refers to general factual knowledge. The hippocampus is a central node in a large bidirectional network that is essential for declarative memory processing of encoding, consolidation, and retrieval. It includes neocortical association regions, subcortical nuclei, the medial temporal lobe (MTL), parahippocampal areas, and the hippocampus itself (Bartsch and Butler, 2013). It receives input from almost all neocortical association areas and the entorhinal cortex. The severe impairment of episodic memory is thought to be caused by hippocampal dysfunction during TGA. It is thought that the hippocampus is involved in the representation of recent episodic memory contents to remote ones by a gradual information transfer from the hippocampus to neocortical structures. Accordingly, the hippocampal dysfunction in the acute TGA state produces a retrograde amnesia as defined by Ribot (1881) who states that remote memories are more robust than more recent memories. Such a temporal gradient in TGA could be shown by Bartsch et al. (2011). Autobiographical memories are considered a part of episodic memory and refer to the recollection of episodes of a person's history, whose temporal sequence, space, and setting can be vividly relived. These aspects are subsumed under the term 'recollection.' Familiarity-based recognition memory (the feeling that the event was previously experienced, typically with spared

Figure 2 Cluster analysis of 63 TGA patients characterizing the three different classes of patients according to their clinical and epidemiological phenotype (Quinette et al., 2006). contextual information) is thought to be supported by extrahippocampal brain regions. It appears to be preserved during the acute state (Jager et al., 2009b). This differentiation between recollection and familiarity is explained by dual-process models that postulate two distinct memory phenomena, which contribute to the recognition of personal experiences; however, alternative models have been suggested as well (Mandler, 1980).

Spatial memory is a further subtype of declarative memory and can also be impaired during TGA. Patients navigating through a virtual water maze performed more poorly than follow-up or healthy controls. Place and reversal learning and retrieval were impaired (Bartsch et al., 2010). Hainselin et al. (2011) further revealed an impairment of prospective memory during TGA, which describes the ability to remember a previously determined intention to act at the right time.

Several memory functions in TGA are preserved during the acute phase, such as priming, sensitization, habituation, and Pavlovian (classical) conditioning. These implicit, non-declarative memory functions are not essentially dependent on hippocampal functioning. Findings concerning affection of working memory during TGA are mixed due to the diversity of paradigms. Working memory is responsible for temporary information storage. It is necessary for complex cognitive tasks such as semantic speech, comprehension, forming a mental representation of the actual environment, learning, and reasoning and is thought to rely on prefrontal processing (Ngo et al., 2012). Working memory is considered preserved in the acute TGA state but there is evidence for impairment in specific executive functions regarding the limits of short-term memory (Quinette et al., 2003).

Taken together, the neuropsychological profile in TGA is a reflection of a hippocampal impairment.

Pathophysiological Mechanisms

The exact pathophysiological mechanisms of TGA are still unclear. The precipitant events, albeit heterogenous, can be subsumed under three higher order clusters that might shed light on the underlying pathophysiological mechanisms: emotional stress, physical effort as well as abrupt temperature change. Three pathogenic main hypotheses have been formulated: a link to migraine-related mechanisms, TGA as an epileptic phenomenon and a relation to hypoxic-ischemic events. Additionally, TGA has been linked to venous flow abnormalities and psychically induced mechanisms (Bartsch, 2012).

TGA and Migraine

Due to its ictal nature, migraine-associated mechanisms have been suggested to be involved in the pathophysiology of TGA (Olivarius and Jensen, 1979; Crowell et al., 1984; Schmidtke and Ehmsen, 1998). Several studies found a higher incidence of migraine in TGA patients (Olesen and Jorgensen, 1986; Schmidtke and Ehmsen, 1998). A prior history of migraine is assumed to be a risk factor for TGA patients younger than 56 years of age (Quinette et al., 2006). Nevertheless, TGA does not seem to reflect an episode of acute migraine because very few patients experience an acute migraine attack before or during a TGA. A key mechanism in the pathophysiology of migraine with aura is a transient wavelike spreading decrease of neuronal activity called 'cortical spreading depression' (CSD). This is a glutamate-mediated depolarization propagating across the cortex at a rate of 3–5 mm min^{-1} in which hyperperfusion is followed by a cortical hypoperfusion. This reversible process can be observed in several pathological conditions such as epilepsy and stroke. In animals, a CSD can also originate in the hippocampus, leading to an altered excitability of CA1 neurons amongst others (Wernsmann et al., 2006). These phenomena could theoretically act as a neurophysiological trigger evoking cellular metabolic changes that eventually result in a TGA, although this has not been shown in humans (Olesen and Jorgensen, 1986). Bartsch and Deuschl (2010) argue that the findings from Wernsmann et al. (2006) based on rodent studies cannot easily be translated to humans given the substantially higher threshold for eliciting a CSD in the hippocampus compared to the neocortex. Moreover, a hippocampal-elicited CSD has not been shown so far in humans. Additionally, patients during an acute TGA state do not exhibit symptoms typical for an acute migraine attack. In summary, the link between TGA and migraine-related mechanisms is controversial. In a comparison between TGA patients and healthy controls, Schmidtke and Ehmsen (1998) did not find an association between TGA and migraine.

TGA and Epilepsy

Certain similarities between TGA and epilepsy suggest a TGA being an epileptic phenomenon. In patients suffering from transient epileptic amnesia anterograde ictal amnesia and persistent retrograde amnesia can be detected. However, most EEG studies in TGA do not confirm this assumption. Epileptic activity was detected neither during the acute TGA state (Bartsch and Butler, 2013) nor after TGA (Jacome, 1989). In addition, relevant symptoms of epilepsy during the acute TGA phase are lacking, such as impaired consciousness and other cortical dysfunctions, automatisms, staring, and motor signs. Also temporal factors (the comparatively short duration of epileptic seizures) and its high rate of recurrence deviate from TGA. Considering the evidence, an epileptic origin of TGA seems rather unlikely.

TGA and Hypoxic-Ischemic Events

Some studies suggested an association between TGA and stroke in terms of a hemodynamic or thromboembolic event (Logan and Sherman, 1983; Felix et al., 2005; and Di Filippo and Calabresi, 2007). Accordingly, TGA came into consideration as a manifestation of a transient cerebral ischemia in memory-relevant structures (Jensen and De Fine Olivarius, 1980). It has also been suggested that in a subgroup of TGA patients, Valsalva-like activities may elicit a cerebral venous congestion (Winbeck et al., 2005). TGA patients show a low incidence of cerebrovascular events after the acute TGA state (Miller et al., 1987; Zorzon et al., 1995; Pantoni et al., 2005). A comparison between TGA patients and patients with reversible ischemic

attacks or lacunar syndrome revealed a statistically significant better prognosis for TGA patients (Haberman, 1984). Enzinger et al. (2008) compared vascular risk factors, magnetic resonance imaging markers of cerebral small-vessel disease, and other evidence of a cerebrovascular disorder between TGA patients and sex- and age-matched healthy controls. Because of a comparable risk factor profile and concomitant changes on brain MRI a cerebrovascular etiology of TGA could not be supported. In terms of the development of dementia, the findings from Gandolfo suggest no enhanced risk for TGA patients. Winbeck et al. (2005) detected an increased intima-media thickness in the common carotid arteries and a higher prevalence of carotid plaques in patients with hippocampal diffusion lesions combining duplex sonography and MRI. This outcome may indicate a higher incidence of atherosclerosis. In contrast, Pantoni et al. (2000) point out that laboratory investigations in TGA patients usually reveal slight abnormalities that presumably correspond to normal aging effects. Several studies compared the cerebrovascular risk factor profile of TGA patients with patients who had a TIA (Hodges and Warlow, 1990a,b; Zorzon et al., 1995) and failed to provide evidence of a connection of high stroke risk factors and TGA. In their metaanalysis, Quinette et al. (2006) confirmed this good outcome.

Stress and TGA

Already in the 1950s (Bender, 1956) a psychogenic origin of TGA was considered. Emotional arousal and stress was identified as a precipitant event in a relevant proportion of patients ranging from 14 (Hodges and Warlow, 1990a,b) to 29% (Quinette et al., 2006). Some patients exhibit emotional changes such as anxiety, helplessness, and depressed mood during the acute phase. Moreover, symptoms of a panic attack (dizziness, palpitations, chest pains, and nausea) have been observed (Inzitari et al., 1997). About 40% of the patients in Pantoni et al.'s (2000) study had symptoms that are typical for panic attacks. They state these patients could be particularly predisposed to hyperventilation during emotionally arousing events, leading to transient changes in cerebral blood flow. Situational circumstances seem to play a role as in about a half of the patients experience a TGA relapse under similar local/situational conditions as during the first TGA attack (Pantoni et al., 2000).

Some authors suggest that states of vulnerability in terms of personality traits like anxiety, phobic attitudes, pathological avoidance behavior, or depressive symptoms as predisposing factors for a TGA (Yesavage, 1983; Neri et al., 1995; Inzitari et al., 1997). Pantoni et al. (2000) point out that psychiatric disorders are more common in the family history of TGA patients compared to controls. It is worth mentioning that more women are affected by an emotionally induced TGA than men, possibly due to their increased vulnerability to affective disorders (Quinette et al., 2006).

Various studies about the impact of emotional changes (depression, anxiety, and stress) on the hippocampus revealed anatomical and functional modifications, leading to certain memory deficits. The hippocampus plays a central role in the glucocorticoid feedback-loop. Acute emotional and behavioral stress enhances the glutamatergic transmission and increases the intracellular calcium influx in hippocampal CA1 neurons. Joels et al. (2009) considers the increased calcium exposure as a potential risk factor for CA1 neurons that elicits a metabolic vulnerability and leads to an impairment of its structural cellular integrity. In the rodent hippocampus, acute stress causes a reduction of long-term potentiation as well as an enhancement of long-term depression, thus affecting hippocampus-dependent memory circuits (Howland and Wang, 2008).

Neuroimaging in TGA

DWI and other imaging techniques (positron emission tomography (PET), single photon emission computed tomography (SPECT)) provide the tool for studying hemodynamic and metabolic changes in mesiotemporal regions that are affected in TGA. The number of reported changes in these studies, however, varies considerably probably due to the sensitivity of the imaging technique and the study time relative to the TGA attack. Several SPECT studies conducted during TGA revealed cerebral blood flow reductions in MTL structures (Stillhard et al., 1990; Takeuchi et al., 1998; Venneri and Caffarra, 1998), however but also in (pre)frontal, occipital, pre- and postcentral areas, and other anatomical structures including the thalamus, cerebellum, amygdala, nucleus lentiformis, and striatum (Lin et al., 1993; Sakashita et al., 1997; Schmidtke et al., 1998; Eustache et al., 2000). Generally, in follow-up analyses the cerebral hemodynamics have returned to a normal state (Lampl et al., 2004).

However, the advent of high-resolution imaging techniques such as magnetic resonance imaging provides a step forward in the anatomical analysis of TGA. Two to three days after the episode, punctuate lesions (1–5 mm) can be detected in the CA1 region of the hippocampal cornu ammonis (Bartsch and Deuschl, 2010) (Figure 3). The detectability peaks between day 2 and 3 after the acute phase. On magnetic resonance spectroscopy, the emergence of lactate in these lesions could be shown that are interpreted as metabolic cellular stress (Bartsch et al., 2008). Lesions resolve spontaneously in the postacute phase within 14 days. Usually lesions outside the hippocampus are not detected.

Due to the fact that neurons of the CA1 region of the cornu ammonis play a key role in the formation and consolidation of memory, these lesions constitute the neuronal correlate of the memory deficit in terms of a transient perturbation of CA1 networks, presumably leading to a functional disconnection of the hippocampus. This assumption is supported by two single case MRI studies during the acute TGA state that uncovered reduced or no activation in temporal lobe structures during encoding and recognition of visual scenes (LaBar et al., 2002; Westmacott et al., 2008).

Summary

TGA is a rare amnesic syndrome known since half a century. The clinical onset is subacute, and mainly characterized by a severe anterograde and retrograde amnesia. After a few hours, symptoms typically resolve. It is diagnosed on clinical grounds and its

Figure 3 High-resolution MRI (3T) in TGA showing typical hippocampal lesions in the CA1 region of the cornu ammonis. Follow-up 6 months after the TGA shows a complete resolution of lesions. Modified after Bartsch and Deuschl (2010), used with permission from Elsevier.

outcome is considered benign. Intellect, personality, and other neuropsychological and cognitive functions remain unaffected. In many cases, certain precipitant events are reported that form clusters referring to physical effort, emotional arousal, or changes in body homeostasis. The etiology of TGA is still cryptic, but hypoxic-ischemic events, migrainelike mechanisms, epileptic activity, and stresslike mechanisms were taken into consideration. Using high-resolution imaging techniques functional correlates of the transient amnesia have been identified: in many patients, focal lesions confined to the CA1 sector of the hippocampus could be detected, a region that plays a major role in the functioning of episodic and autobiographical memory, place memory, prospective memory, and others. However, this region is also vulnerable to oxidative and metabolic stress.

Transition to Adulthood

Maria Sironi, University of Oxford, Oxford, UK

Abstract

The process by which adolescents and teenagers face the transition to adulthood has changed substantially in the Western developed world. This is one of the demographic transformations that have occurred in the last 50 years, and can be framed in the second demographic transition theory. In this work the main changes in the life course trajectories of young adults are highlighted, and the differences across gender and social class are described. Also, the role of institutions and culture in shaping the transition to adulthood is taken into account.

Introduction

The second half of the twentieth century has been characterized by substantial changes in demographic behaviors. Developed countries have witnessed large decreases in fertility, with a very recent reversal of the decline (Myrskyla et al., 2009), a strong reduction in marriage rates or at least a postponement of family formation, and an increase in the prevalence of cohabitation and divorces (*see* Partnership Formation and Dissolution in Western Societies). Among these important transformations, also the process by which adolescents and teenagers transition to adulthood has changed greatly in many – if not all – countries in the Western developed world. Typically, the demographic events of adult transitions have included such markers as leaving home, finishing education, securing a job, marrying or cohabiting, and having children. In the postwar years, all the events in the transition occurred quickly (usually by 25 years of age for both men and women) and in an orderly sequence beginning with school completion, full-time work, and home leaving. Since then, the transition has lengthened and become more complex.

All the events of the transition to adulthood have been delayed (Aassve et al., 2002; Furstenberg, 2010), and it is important to take into account their interdependence and strong interactions: there has been a substantial expansion of education, especially among women, leading to an increase in the age at school completion. This increase may be correlated to a later entrance in the labor market and a delay in leaving the parental home – at least in some contexts (e.g., southern Europe). A postponement in the achievement of independence (monetary and nonmonetary) from the family of origin can be to some extent associated to or be responsible for a later age at family formation, i.e., cohabitation, marriage, and parenthood.

Moreover, individuals had to adapt their life course trajectories because of profound structural and cultural changes (such as the globalization process and a decline in the normative imperative to marry) occurred in developed societies in the last decades. As a consequence, these trajectories have become more diverse. The 'second demographic transition' theory would use the term *individualization* to characterize changes in the life course (Lesthaeghe, 1995), which includes many different aspects, such as the deinstitutionalization, the destandardization, and the differentiation in the life trajectories of young adults. The order and the timing of events may vary considerably between individuals, as well as the duration in different states (*see* Life Course: Sociological Aspects). When studying all these trends it is necessary to consider that changes are not uniform across countries (and welfare states), across social classes and there are also large differences by gender (Buchmann and Kriesi, 2011; Sironi and Furstenberg, 2012).

There is much public debate about why the transition to adulthood changed so suddenly, and social scientists have not yet reached consensus on this question. An increase in the years of schooling may cause a delayed entry in the labor market; over time the structure of the labor market itself could have changed so that well-paid jobs require more education and are therefore more difficult for young adults to find (Danziger and Ratner, 2010). Increases in earnings inequality, employment instability, and shortening of job tenure due to higher turnover are some of the most relevant changes that have occurred since the 1970s. Together with these structural changes, youths' expectations about what it takes to live independently have risen, along with the actual costs of living. Moreover, the normative and cultural shifts that have taken place in the second half of the twentieth century may also contribute to an increase in the heterogeneity characterizing individual life courses (Arnett, 2000; Lesthaeghe, 1995; Van de Kaa, 2001). The post-1960s shift in sexual attitudes and practices, for example, has also slowed what was once a rush into adult roles. Fifty years ago, premarital sex was still highly stigmatized. Although the stigma did not deter many young couples from breaching the norms, marriage served as a safety net in the event of a premarital pregnancy. Also, although today's young adults and their parents' value independence highly, both tolerate and even endorse a slower schedule for attaining economic and social maturity (Arnett, 2000).

The transition process has traditionally been considered as complete when an individual has experienced all events – completion of education, labor market entry, leaving the parental home, forming a union, and entry into parenthood. This idea has been questioned in recent years, for example, by Arnett's (2000) concept of emerging adulthood, a new developmental stage in the life course. Between adolescence and adulthood, this stage is characterized by long-lasting explorations of identity, lifestyles, and career possibilities (Arnett, 2000; Buchmann and Kriesi, 2011).

Recent Findings: Have the Changes Been Equal for Everyone?

Overview

Recent studies on the transition to adulthood in Europe and, more generally, in developed countries, found some common trends. First of all, the process leading to adulthood has been prolonged. This means that not only most of the events have been delayed, but also that the time span from the first event (usually the completion of education) to the last (usually childbearing) is now much longer (Aassve et al., 2002; Billari, 2004). Secondly, all countries have experienced increasing diversity at the individual level, the so-called trend of 'converging divergences' (Blossfeld et al., 2012; Mills et al., 2008).

The expansion of education, that has characterized the last five decades in developed countries, has raised the median age for completing schooling and contributed to the delay in the age at which young adults start working (Schizzerotto and Lucchini, 2004). The median age of completing their education among cohorts born in the 1950s in Great Britain, Germany, and Italy, for example, was 16 years, but it increased to 17 years for cohorts born in the 1970s in Great Britain and Germany and to almost 20 years in Italy (Buchmann and Kriesi, 2011; Schizzerotto and Lucchini, 2004). The proportion completing upper secondary (90%) and tertiary education (40%) is high in the United States among those born in the late 1960s and 1970s. The figures are even higher in Scandinavian countries, where the completion rate of tertiary education approached 50% in 2007 (OECD, 2009).

In addition, the structure of the labor market itself has changed significantly amid global competitive pressure, leading to instability of labor markets and greater difficulties in finding a job – another cause of the delay (Brzinsky-Fay, 2008). Since the 1970s, earnings inequality and employment instability have grown and job tenure has declined with growing turnover (Sironi and Furstenberg, 2012). Among people born in the 1950s, the median age at first job was between 16 and 19 years. Among those born in the 1970s, the median age was between 19 and 24 years in developed Western countries (Schizzerotto and Lucchini, 2004). Young adults in southern Europe often experience a period of career instability when they exit education, and youth unemployment is highest in those countries. The entry into the labor market is easier and faster in Continental countries, while liberal and Scandinavian countries occupy an intermediate position (Quintini et al., 2007). In fact, in northern Europe young people may experience high unemployment and uncertainty immediately after school completion, but only for a short time.

The departure from the parental home marks the beginning of social independence (if not financial). The age of leaving has increased with time, but the postponement has been modest in most countries. Southern Europe is the exception. There the median age of leaving has risen substantially. In northern Europe, young adults leave their family of origin very early, before 20 years of age. In continental and liberal welfare states, individuals leave on average in their early 20s, while in countries such as Italy, Spain, Portugal, and Greece, young people in their late 20s or early 30s (Aassve et al., 2002; Billari, 2004).

One of the main steps leading to independence is financial self-sufficiency. In many countries, in the 1990s, only a minority of young people is able to support themselves in their late teens and early 20s with their earnings alone. Even when social transfers were taken into account, a significant proportion of young people are unable to support themselves, much less a family, before their mid-to late 20s (Smeeding and Phillips, 2002). This issue has worsened over time, and some studies found a declining economic self-sufficiency in the last two decades. Only women in their late 20s and early 30s saw somewhat improved prospects, even though their earnings remain below men's (Sironi and Furstenberg, 2012).

Finally, a strong postponement and eventually a total foregoing, have been observed in family formation. The mean and median age at first marriage have increased in all developed countries, and more frequently marriage has been substituted by cohabitation (Billari, 2004). Age at first birth has increased by 3–5 years in the last four decades (Sobotka, 2008), and also the total fertility rate has decreased, even though not equally in all countries and with a recent reversal of the decline (Myrskyla et al., 2009).

Differences across Gender and Social Classes

Notwithstanding this general trend of postponement, the changes in the process leading to adulthood have not been uniform across gender and social class (*see* Class: Social; Social Stratification).

The relevance of family social class on the subsequent life course starts before birth, it continues throughout adolescence, and it is able to shape the course of young adult transitions and psychological development in the third and fourth decades of life (*see* Socialization in Infancy and Childhood). Youth from affluent and well-educated families marry and have children later in life because of a longer education, much more extended search for a permanent partner in life, and a lower incidence of unintended pregnancy (Furstenberg, 2010). Young adults from disadvantaged families, even if they go to college, do it with fewer resources and therefore face more difficulties in completing the degree. Moreover, they do not want and cannot afford to remain unemployed for too long, and consider education as a way to get a job. So they are more likely to drop out of school if they are able to find an occupation. Finally, the economic difficulties linked to the housing costs, may hinder the independent living before family formation. Family background can influence not only the timing of events in the transition to adulthood but also the sequencing of these events thus modifying the propensity to experience traditional or innovative patterns. For example, children from higher family social status, on the one hand, tend to postpone their first union and their first child birth (Rijken and Liefbroer, 2009); on the other hand, tend to acquire their housing autonomy earlier, without directly making the transition to live with a partner (Blaauboer and Mulder, 2010).

The employment and earnings changes of the past four decades have affected the transition to adulthood in ways that vary sharply by gender. Education expansion has been more substantial among women, who started from a lower level and caught up with men in earning college degrees and enrolling in graduate studies. Increases in the labor force participation rate have also been much more pronounced

among women (Danziger and Ratner, 2010; Sironi and Furstenberg, 2012). The changing economic situation of young men and women has implications for the second phase of adult transitions: union formation and parenthood. Career opportunities and earnings, in fact, affect men's and women's decisions about marriage and parenthood differently. Among men, steady employment and earnings are positively associated with marriage and childbearing. For women, the picture is less clear. The new home economics hypothesis (Becker, 1965) states that women's economic independence is the main reason behind delayed marriage and motherhood in industrialized countries. Gains from marriage and role specialization within marriage dissipate with women's growing investments in human capital and careers. The higher their level of education and the better their job opportunities, the more likely women are to postpone or even avoid marriage and motherhood. An alternative hypothesis, with different implications, is that women's earnings contribute to a couple's higher standard of living, which encourages marriage (income effect). Which scenario dominates is not clear yet and appears to depend on other factors, such as local and country context, birth cohort, and educational attainment (Harknett and Kuperberg, 2011).

Cross-National Differences: the Role of Institutions and Culture

The main issue concerning changes in the transition to adulthood over time is the lack of convergence in life course patterns in different countries (Liefbroer and Goldscheider, 2006). It has been argued that the lack of convergence may stem from differences in labor market regulations, welfare regimes (and so in the diversity underlying institutional structures), and cultural aspects such as family ties. Both institutions and culture influence life course trajectories, creating prospects and constraints to which people adapt (Breen and Buchmann, 2002).

Different types of welfare regimes can influence individuals' behavior; especially their 'demographic' decisions (Esping-Andersen, 1990) (*see* Welfare State, History of). The four regimes in the West include the *social democratic* welfare state (Scandinavian countries), characterized by high levels of state support and a focus on the individuals. The *conservative* welfare state provides generous support for the family rather than the individual (for example, in France and Germany) and thus reinforces family ties. The *liberal* welfare regime provides a modest level of means-tested benefits, applicable only in case of inefficient markets, and oriented to individuals (examples include the United Kingdom and the United States). The fourth category includes the southern European countries with their strong reliance on the family as the locus of support and low levels of welfare provisions from the state (Trifiletti, 1999). Eastern European (former communist) countries have not yet been systematically included in comparative research, and could be considered as a new and interesting research field.

Each regime is associated with a different transition to adulthood. In social democratic countries, for example, labor market entry and leaving the parental home should take place at relatively younger ages owing to generous social benefits, which provide more certainty about future economic conditions. In conservative and liberal countries, it is difficult to predict a typical life course trajectory, but one would expect a lower destandardization and variability of life courses than in Scandinavian countries. In contrast, southern European countries should show late exit from parental home, late marriage, and childbearing, given the lower level of benefits and resulting stronger dependence on the family of origin (Aassve et al., 2002; Billari, 2004; Esping-Andersen, 1990; Mills et al., 2008).

As far as family support is concerned and cultural differences more generally, the initial conditions from which modern societies have developed are fundamental for the present differences in behavior. More precisely, in southern Europe, the influence of Islam raised the importance of kinship and vertical relationship between generations, so that the prolonged stay of children in their parents' home and the caring work of children toward their parents are two faces of the same coin, a 'strong' family. In the north, Germanic tradition and the reformation contributed to the development of a 'weak' family (Reher, 2005). Empirical evidence supports these views, finding that the share of young adults who are financially dependent on their parents and family members is much larger in southern Europe (Billari, 2004). The cultural inheritance model (as the welfare regimes explanation) predicts that convergence will not take place at a national level: factors, which lead to homogenization of behaviors throughout the world, like those implied by modernization and economic globalization, will not have the same impact on societies with different cultural and historical origins, thus leading to diverse and possibly divergent coping behaviors and timing of transitions.

Macro Typologies of Life Course Trajectories

Based on the findings of the current literature on the transition to adulthood and on the possible determinants of cross-national differences just described, it is possible to identify four different macrocategories of life course trajectories. Each one includes different countries of the developed Western world. In order to make the distinctions easier to understand for the reader the characteristics of each typology are reported in **Table 1**.

It is important to note that these categories are not exhaustive of all the experiences reported in developed societies, and that part of the empirical evidence does not match well within these groups. This may be partly due to the influence of short-term economic fluctuations, recent policy changes, and the increase of migration flows that might alter the composition of national populations. Also, it is possible that the way in which welfare regimes and culture impact demographic behavior is not exactly as predicted by the theoretical arguments. Hence, further research is required to better understand the role of macro characteristics, as institutions and family ties.

Conclusions

The transition to adulthood is a complex concept, and the complexity has certainly increased over time with the emergence

Table 1 Typologies of the transition to adulthood

Group of countries	*Welfare state*	*Culture and family ties*	*Independence transition*	*Family formation*
Scandinavian countries	Welfare rights and benefits granted as individual entitlements; unemployment benefits available for young people.	Weak family ties that imply individual's priority over the family.	High completion rates of tertiary education and widespread vocational training promote easier labor market access. High importance of young people's autonomy, very early home leaving.	Early nontraditional union formation (mostly cohabitation); late age at marriage (if any). Great heterogeneity in the age at entry into parenthood.
Liberal countries	Strong market orientation, loosely regulated labor market; means-tested benefits oriented to individuals.	Weak family ties, strong focus on self-reliance and autonomy	Weak regulation of the labor market supports an early completion of schooling and easy access to the labor market (even with high instability); early home leaving, early school completion, and entry into the labor market.	The early 'independence' transition facilitates early family formation. Possible delay in family formation in times of greater instability of the labor market.
Continental/ Conservative countries	Welfare transfers oriented to families.	Stronger family ties than in liberal and Scandinavian countries that are reinforced by family-oriented welfare transfers.	Strong vocational education system; easy access to the labor market even if at later ages. Later age at home leaving and achievement of economic independence, but with more stability.	Family formation shortly after the achievement of financial self-sufficiency, given the greater stability in the labor market. The postponement of economic and employment stability may be a cause for delayed home leaving
Southern Europe	Weak welfare state transfers, mainly family-oriented.	Strong family ties; family is the locus of support for young people.	Late age at school completion and no vocational training hinder an easy access to stable jobs; strong senior worker protection; Very late age at home leaving.	Having a stable job and economic self-sufficiency are important conditions to form a family, so also age at union formation and parenthood are higher than in other countries.

of new and heterogeneous behaviors. What is clear is that a common trend is taking place in all developed societies: a deterioration in economic and employment conditions among young adults. This is true in all countries among men, while in some context there has been an improvement in women's participation to the labor market with some positive influences on their attainment of financial self-sufficiency (Sironi and Furstenberg, 2012).

This phenomenon, that started in the second half of twentieth century as part of the second demographic transition, is bringing to a convergence in life course trajectories across gender that may have important implications for the subsequent steps like family formation. The consequences of these changes in the first steps of the transition – that somewhere are not the same across gender – should be examined in future research, especially their effects on the timing of first unions and childbearing. A delay in the achievement of independence among men is likely to produce a delay in union formation and parenthood, while an increased education and labor force participation among women could have positive effects on this life domain. The positive effects are strictly dependent on the ability of policies to adapt to these changes, and to be flexible enough and allow women to combine work and family life (McDonald, 2000).

This issue is strongly linked to the methodologies that are usually used to study the transition to adulthood. Most studies, both comparative and noncomparative ones, focus on a specific phase of the life course trajectories, if not on one event only. Very often the departure from the parental home is the key event of the analysis, some research focus on the transition from school to work, and some others only on family formation. However, the life course paradigm assumes that individuals, as human agents, build their future on the basis of the constraints and opportunities experienced in the past. The process is iterative and cumulative, since initial advantages or disadvantages often are amplified with time (Giele and Elder, 1998). Life courses are embedded in different time and location and are affected by the social context in which individuals live. In addition, different life domains are strongly interdependent. Hence, it is important that life course analysis looks at the whole life trajectory. Under this perspective, characteristics such as type, number, duration, and order of events should be all taken into account. Only a limited number of studies adopt a complete life course perspective. Future research should exploit the already existing methodologies (e.g., sequence and latent class analysis), and also refine them or develop new ones that allow to capture the complexity that is inherent in a phenomenon like the transition to adulthood (Barban and Billari, 2012).

Abstract

Of interest is the transition to adulthood in non-Western cultures according to culture-based mechanisms including rites of passage. Cultural markers of transition are reviewed according to those that are biologically based, those that include ceremonies and celebrations, and those that involve instruction. The changing nature of these markers is discussed in light of globalization.

Introduction

It is commonly stated that adolescence begins with biology and ends in culture. The biological mandates of physical growth and sexual maturation at the onset of adolescence are universal, but what is less uniform is the cultural management and meaning of biological pubescence. Of additional variability and ambiguity are the sociocultural indicators that signify the transition from adolescence to adulthood. The social experience of adolescence as a life stage has been shown to be nearly universal in Schlegel and Barry's (1991) landmark analysis using the standard cross-cultural sample. Further, a stage of youth exists in many cultures – a somewhat comparable time period applicable to later adolescence which today is called emerging adulthood (Arnett, 2007; Schlegel, 2009). The focus of this article is on the culture-based markers of the transition from adolescence to adulthood in current non-Western societies. Of particular interest is the degree to which traditional rites of passage and culture-based rituals are changing and modified due to globalization.

A useful starting point is to define what is meant by 'transition to adulthood.' The National Research Council and Institute of Medicine (NRCIM, 2005) assessed the sociodemographics of this transition in developing countries and pointedly concluded that the transition is presently experienced by more young people than ever. The social markers of adulthood are distinctive features accomplishing this transition compared to the biological markers of transitions of earlier stages of development. The shift from being dependent upon to becoming independent from parents is a key overall indicator of successful transition to adulthood as well as providing for one's own needs as well as the needs of others (Hamilton and Hamilton, 2009). It is through a society's institutions (i.e., education, employment, civil society, and family) that the transition from adolescence to adulthood occurs (Hamilton and Hamilton, 2009). Jeffrey and McDowell (2004) identify the changing global order – particularly related to economic factors – that makes today's transition to adulthood particularly complex.

Of further consideration is how the transition to adulthood varies between Western and non-Western cultures. In Western cultures, there are various chronological age markers conferring adult privileges, such as freedoms and responsibilities associated with driving, voting, consuming alcohol, and being accountable as an adult relative to the criminal justice system. The current trend is for adolescence to morph into emerging adulthood (approximately ages 18–25) during which time individuals acquire all societally derived adult privileges, but do not yet demonstrate complete adult autonomy in all areas (Arnett, 2007). Hence, while legal privileges are conferred early in this time frame, adult attainment relative to completing education, financial independence, and marriage and long-term emotional commitments, such as parenting, vary greatly. Cross-culturally, delays in the age of marriage are a key indicator that the transition to adulthood is now later than times past (Hamilton and Hamilton, 2009). This factor is heavily linked to economic viability which is a facilitator of marriage.

Emerging adulthood may not be an applicable stage concept in impoverished and developing countries' cultures due to constraints in time and resources for adolescent experimentation in relationships, lifestyles, and careers that limit opportunities to have and enact choices (Markstrom, 2011a). Further, emerging adulthood implies a quality of Western individualism which may not be consistent with communal/collectivistic values of some cultures considered in this article. Nonetheless, adolescents worldwide are becoming increasingly exposed to diverse pathways of careers and lifestyles. In cases of favorable economic conditions, emerging adulthood may acquire more relevance in some non-Western cultures.

Globalization is a weighty consideration in this article because most of the current writings on the transition to adulthood in non-Western cultures consider cultural changes due to globalization. Globalization and Westernization (one domain of influence of globalization) are advanced through present-day media exposure including the internet and social networking sites, as well as increased travel. Certainly, there is variability in access to global ideas due to socioeconomic status, rural/urban living status, educational opportunities, and related factors. However, with greater global awareness, losses relative to local language and cultural traditions may occur including those attached to the transition to adulthood.

Youth are active participants in globalization (Larson et al., 2009). Due to greater maturity and autonomy, unrestricted access to global ideas and products, social opportunities outside of the family, identity exploration, and the quest to position themselves in the world around them, adolescents are keenly interested in new ideas and opportunities (Jensen and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23214-5

Arnett, 2012). The global media is a prime source for adolescents across cultures providing direct, unrestricted access to information (Schlegel, 2000). Due to trends and ideas in fashion, music, language, and ideas, the notion of a more pervasive and somewhat homogenized global youth culture is not far-fetched. Hence, identifications to local culture may be supplemented, transformed, or in some way altered leading to bicultural, multicultural, and hybrid forms of identity. Certainly, there is the potential for confusion as identity formation at the local level is managed vis-à-vis different and potentially conflicting information from global sources. Changes to the performances of traditional rites of passage are inevitable – we are not assuming that these rituals are simply relinquished but rather managed and transformed in various manners.

The next section reviews classic models of rites of passage within the topic of the transition to adulthood. Then, several illustrations of changing cultural practices or markers of this life transition are reviewed, i.e., traditional ceremonies and practices that serve to usher in the transition into adulthood. This article closes with overall discussion on the changing themes of transition to adulthood in non-Western cultures according to globalization.

Rites of Passage and the Transition to Adulthood

Of primary interest in this article are cultural markers of the transition to adulthood – specifically as occurring in non-Western cultures or subcultures within Western cultures. Cultural markers encompass traditions, ceremonies, and rites of passage that facilitate change at particular times in the life span. The term 'initiation' also applies and, particular to adolescence, Schlegel and Barry (1980) defined initiation as "some social recognition, in ceremonial form, of the transition from childhood into either adolescence or full adulthood" (p. 698). In traditional societies of the past, more often small societies, such ceremonies occurred anytime during late childhood or adolescence (8 and 18 years of age) with most occurring around puberty. At adolescence, the more specific functions of rites of passage surround the idea of growing to adulthood (see **Table 1** for a list of functions).

Initiations may take the form of rites of passage which are ritually linked activities that occur in conjunction with major life events, such as birth, coming-of-age, marriage, and death. They serve many functions that span psychological (e.g., altered self-perception), social (enhanced connections to the social group), and ethological (e.g., assignment and classification of gender roles) explanations (Schlegel and Barry, 1980). The classic van Gennep (1908/1960) rites of passage model includes three sequences of separation, transition, and incorporation. With separation, the initiate is symbolically or physically removed from the mundane rhythms of his or her society (either alone or with other initiates depending on the culture). Separation does not necessarily equate isolation, but rather it is some form of distancing from the everyday or ordinary in order to progress into the extraordinary of the transitional sequence of the rite of passage. Transition can be a psychologically discomforting experience because classification according to previous life identifications is not available nor has the individual been conferred to the next stage of life (Turner, 1967). A rite of passage in many North American Indigenous cultures was the vision quest or the Walkabout practiced among Aborigine Australians. Initiates were required to be physically isolated (separated) and engaged in fasting and prayer during the time of transition to facilitate spiritual transcendence through the acquisition of a vision. In some cultures, rituals entailing bodily adornments, such as special clothing or tattooing, prayers, and instruction and mentorship also occur during transition (see **Table 2** for illustrations of rituals of transition). With successful accomplishment of the rituals of transition, the initiate becomes incorporated into the stability of everyday life but at a new social stage with accompanying responsibilities. Ultimately, rites of passage serve a strong social conveyance function that informs the initiate and his/her social group that an important social change is occurring.

Table 1 Examples of functions of adolescent initiations and rites of passage in various cultures of the world

- To compel the initiate to accept desired social roles.
- To announce marital eligibility of the initiate.
- To ascribe a socially valued identity on to the initiate.
- To encourage the initiate to exhibit discipline, maturity, and social responsibility.
- To compel the initiate to assume expected social and behavioral changes in accordance with physical maturation.
- To facilitate the initiate's inculcation of cultural values, beliefs, and practices.
- To compel the initiate's adoption of desired character traits related to disposition and temperament.
- To promote the initiate's longevity.
- To recognize and celebrate change of status in the initiate's life.
- To advance reproductive viability or fertility of the initiate.
- To solidify and strengthen kinship and other social bonds between the initiate and others.
- To facilitate spiritual enhancement or transcendence of the initiate.
- To build physical strength and endurance of the initiate.

Adapted from Markstrom, C.A., 2011b. Initiation ceremonies and rites of passage. In: Brown, B.B., Prinstein, M.J. (Eds.), Encyclopedia of Adolescence, vol. 2. Academic Press, San Diego, pp. 152–159.

Table 2 Examples of rituals occurring during the transition phase of rites of passage in various cultures of the world

- Apprenticeships
- Bathing
- Capping
- Changing of clothes
- Dancing/singing
- Ear piercing
- Fasting
- Feasting/lavish parties
- Genital mutilation
- Hair cutting/head shaving
- Hair pinning
- Hand washing
- Henna painting rituals
- Tattooing
- Inducting into a secret society
- Praying
- Wearing turbans/head scarves

Culture-based rites of passage practiced in the transition to adulthood in Western societies are limited. Certainly ceremonies such as graduation from high school or higher education do confer a measure of maturity with marriage bringing even further adult distinctiveness. Some adolescents may undergo religion-based rites of passage such as Jewish *Bar Mitvahs* and *Bat Mitvahs* and Protestant and Catholic religious confirmation ceremonies. These ceremonies of commitment, confirmation, and initiation teach and elicit commitments of fidelity to a belief system (Markstrom, 2008). In contrast, the remainder of this article addresses rites of passage and other markers of the transition to adulthood in non-Western cultures where such practices may represent more culture-embedded practices. Of further consideration are changing customs in an increasingly globalized world.

Cultural Markers of the Transition to Adulthood

Examples of cultural markers of transition to adulthood are organized according to those that are biologically based, those that include ceremonies and celebrations, and those that involve instruction. The reinvention and revisions of these markers are considered according to exposure to global ideas.

Biologically Linked Markers

Genital Mutilation

Genital mutilation is a marker of a new status, albeit a highly controversial marker. Female genital mutilation (FGM), also termed as female cutting or female circumcision, is one type of genital mutilation and is defined by the World Health Organization (WHO, 2008) as "all procedures involving partial or total removal of the external female genitalia or other injury to the female genital organs for non medical reasons" (p. 1). UNICEF (2013) estimated that 125 million girls and women in 29 African and Middle Eastern counties have undergone FGM. Although there have been decreases in the rate of FGM, UNICEF suggests that about 30 million girls are still at risk of experiencing it in the coming decade. Reasons for the persistence of FGM include desires for the protection of ethnic and gender identity, female sanctity and virginity, family prestige, hygiene, and ensuring matrimony (UNICEF, 2013). FGM practices have complex etiologies and are rooted in ideological, material, and spiritual reasons for those that practice them (Berg and Denison, 2013).

FGM is a divisive issue and has sparked international outcry asking for its abandonment as a practice. As a result, these rituals have been modified and eliminated in many traditional cultures due to social and health concerns. For instance, rising rates of HIV/AIDS in Africa is forcing communities to reshape the goals and social capital rooted in cultural rituals such as circumcision (Kang'ethe, 2013). There have also been reports of sterile procedures being introduced in both male and female circumcisions (Kang'ethe, 2013; Prazak, 2007). African practicing communities, in attempts to hold on to their cultural values, norms, and belief systems, have added alternative approaches and rituals. For instance, Oloo et al. (2011) discuss 'alternative rituals' used in Kenya with varying degree of success. Components of these rituals included periods of teaching, frequently occurring in isolation, as well as communal festivities and sometimes a certificate to indicate the completion of the rituals. The alternative practices focus on retaining the essential components of female circumcision, such as instruction about duties and roles in the home, gift exchange, festivities, and public acknowledgment of the change of status, in the absence of the cutting ceremony. These alternative rituals help girls acquire knowledge about reproductive health and promote perspectives on gender equality in the family and among community members.

Cross-national migration has also contributed to the changing face of genital mutilation across the globe. Berg and Denison (2013) stated that the legal frameworks and national discourses in Western countries have served as barriers to immigrants' practices of FGM. Some from these immigrant communities now question the practice in their new social, political, and cultural contexts while some argue for its necessity as a cultural tradition (e.g., Isman et al., 2013).

Menarche and Pubertal Development

Rituals of genital mutilation often are associated with the changing pubescent, but there are other types of cultural practices during this phase of transition. Albeit these markers occur early in the developmental transition to adulthood and, today, do not necessarily confer full adult status. Nonetheless, cultural markers at pubescence advance recognition and celebration that the individual is moving toward adulthood. Markstrom (2008) conducted extensive research on contemporary practices of female coming-of-age ceremonies at menarche among various North American Indian tribes. The Western Apache Sunrise Dance and the Navajo Kinaaldá are two ceremonies with continuity in practice over eons. Adolescent initiates are similar to their counterparts throughout the present-day United States – they attend school, they engage with social media, they listen to popular music, they wear the same trends in fashion, and so. Yet, for a sequence of several days, contemporary life is suspended and a physical context is constructed with resemblance of earlier ways of their ancestors. These ceremonies reflect a remarkable coexistence of present-day life suspended for a brief time while ancient rituals are implemented with seemingly minor changes from the past (Markstrom, 2008). Transition is ushered in through complex and physically and emotionally challenging rituals richly imbued with meaning and reflective of important cultural values. Traditional beliefs, values, and practices are reinforced through the retelling of origin stories, speaking of the language, preparing and consuming traditional foods, incorporating traditional sacred objects into rituals (e.g., feathers), and wearing of traditional clothing (Markstrom, 2008). Apache, Navajo, and similar ceremonies of other tribes facilitate spiritual transcendence so that the initiate is empowered and prepared for challenges of contemporary life that will require her management. Ultimately, the initiate returns to her everyday life but with a new social status and altered self as well as other perceptions.

Social treatment of pubescence has also been examined within the fluidity of the ever-changing political and socioeconomic contexts of African cultures. In indigenous Africa, the community takes responsibility for socialization of youth and engages in ceremonial rituals to support the youth's transition

from adolescence to adulthood. With Western influences, many pubertal rites of passage are changing or being eliminated completely (Adegoke, 2001). For example, in Kikuyu culture, adolescent girls only had contact with young men other than their brothers at the Ngweko dance which was monitored through peer supervision. The dance also functioned to formally transfer from parents to youth the responsibilities of premarital sex and mate selection all within a supportive context. Today, adolescent girls interact with males within school contexts in the absence of norms and instructions for their behavior with the opposite sex (Adegoke, 2001).

Pubescence is an obvious biological marker that has been the focus of intensive and extensive ceremonial rituals and rites of passage for mostly girls and also for boys in certain cultures (Schlegel and Barry, 1980). These events at pubescence and other time frames during adolescence are accompanied by rituals and frequent celebrations, of which some examples are given in the next section.

Rituals and Celebrations

Bodily Adornment

van Gennep (1908/1960) situated bodily transformations such as tattooing, scarification, or painting within rites of passage. Separation can be heightened by rituals of bathing and hair washing, changing of clothes, tattooing, and other physical alterations. Margret Mead (1928) described adolescence in her book, *Coming of Age in Samoa*, drawing attention to the Samoan tattooing ritual to signify the commencement of adolescence. However, this tattooing ritual in Samoa has diminished over the years with the presence of Christian missionaries, rise of education, and immigration for jobs. But a resurgence of tattooing has been seen among those who remain in Samoa as a separation response to the forces of globalization in Samoan society (Jensen and Arnett, 2012).

Revival of bodily adornment rituals has also been seen among immigrants who display bicultural identities. This is often an effort to preserve culture of origin as individuals assimilate into their new cultures after immigration (Phinney et al., 2001). For example, the bride's henna ritual practiced by Jews in Yemen and its subsequent transformation after their immigration to Israel (Sharaby, 2006) which illustrates the negotiation of bicultural identities among immigrants. The henna ritual was seen as a seminal rite of passage for women in Yemen and as a way of conserving societal institutions which promoted gender separation and non-egalitarian structures in society. In the past, only women participated in the ceremonies and singing and dancing gave women a space to challenge the rules of modesty and social norms that governed their lives. Moving to Israel, coupled with shifting from extended to the nuclear family system, exposed Yemenite women to new economic and social activities. There have been major alterations to the henna ritual as a way to renovate a traditional ritual to fit the shifting social and cultural context for young immigrants; for example, the wedding henna ritual has been reinvented to focus more so on the couple's change of status, instead of just on the woman's rite of passage as she transitions into a man's wife (Sharaby, 2006).

Youth Galas

The glamorization of the prom in the Bahamas is an interesting example of the influence of globalization on the youth of a non-western culture according to a hybrid ritual that combines elements of traditional culture, postcolonial reactions, and influences from the United States (Thompson, 2011). The celebration of proms in the Bahamas was initiated as a response to their independence from the British in order to find new ideals of modernity – it serves as a coming-of-age practice for Bahama's own youth. Proms were initially celebrated in hotels as low-key events; however, they have evolved into something much more dramatic among Bahamian youth culture. The popularity of American television, the American expatriate community, and even its close proximity to America allows for an easy flow of hip-hop culture to Bahamian youth. This influence has led proms to transform into something of a spectacle, especially prom entrances. The desire of youth attending the prom is to be seen in the most spectacular way possible with tricked out cars, flashy bling, and elaborate prom wear (Thompson, 2011). However, components of cultural heritage also are evident. For example, while Western style prom dresses are worn by some prom-goers, others choose to dress in more elaborate costumes reminiscent of Caribbean stylings. Overall, this hybrid celebration provides space for expression of meaningful cultural traditions as well as youth customs imported from elsewhere.

Quinceañera

Another example of an elaborate youth celebration is the Latina quinceañera at the time of a girl's 15th birthday. The young female wears an elaborate or elegant dress, traditionally white, and has a 14-member court that serves as a symbolic representation of her 14 years of life. In the past, the quinceañera has been practiced in Latina/Hispanic Catholic communities as a symbol of the girl's readiness to marry. Within the Catholic Church, this right is very important and is considered an extension of baptism for the girls. The quinceañera emphasizes the importance of virginity and community service, but it has been changing (Banuelas, 1981 as cited by Davalos, 1996). Today, quinceañeras signify the parents' acknowledgment of their daughter's readiness to date, and has been transformed into something more similar to a 'sweet-sixteen' party rather than the entrance into womanhood function of the past (Davis et al., 2009). In Ecuador, quinceañeras are losing their celebratory extravagance in favor of other types of extravagances such as expensive gifts or foreign vacations for the girls (World Trade Press, 2010). Among Protestant Mexican-Americans in the United States, the quinceañera ceremony has been redefined as a cultural rite of passage rather than a Catholic rite (Barton, 2006). With the influence of American culture, the quinceañera has been expanded into something akin to a wedding with the associated high costs, advanced planning, and encompassing a cultural significance rather than being defined solely on religious grounds (Dieter, 2002). Further, in some cases, the quinceañera has begun to be identified as a debut or sweet-sixteen celebration. Although the extravagance and religious and cultural significance are changing, the quinceañera is still an important part of a girl's transition into womanhood for many Latina/Hispanic cultures in the United States.

Marriage

Marriage is a formalized event that brings recognition, meaning, and significance to life transitions as a rite of incorporation. It has universally been regarded as a rite of passage to adulthood. However, the United Nation's World Marriage Data (2008) shows that since the 1980s, marriage rates have decreased in countries that encompass a total of 87% of the world's population. This trend suggests a global decline in the rates of marriage, which further affirms the changing face of coming-of-age in the twenty-first century. Emerging adulthood has been often cited as a reason for postponing marriage and parenthood in industrialized nations (Jensen and Arnett, 2012), where it has been primarily studied. There is a further need to study marriage and emerging adulthood in collectivist cultures like India or China as together they represent 42% of the population of young people in the developing world (NRCIM, 2005), which increases their influence on global youth trends.

An interesting case study of Indian youth reveals how young urban professionals navigate two identities: one that participates in an international economy and the other that seeks to adhere to Indian traditions such as arranged marriages and caring for their parents in old age (Verma and Saraswathi, 2002). However, it is important to consider that these social norms surrounding community and kinship, coupled with the structural constraints of poverty, shape the lives of youth in rural India very differently than their urban counterparts. Disparities in employment, education, and healthcare between urban and rural youth continue to be a persistent problem in present-day India (Patel, 2013). Additionally, India also struggles with child marriages, which UNICEF (2007) defines as marriage prior to age 18. Child marriages show considerable variability across countries; nonetheless, about half of those experienced are by girls in South Asia (UNICEF, 2007).

Marriage and family are also highly valued in China, where influences from Confucianism along with tumultuous economic and social reform movements contribute to an understanding of the role of these institutions in young people's lives today (Yeung and Hu, 2013). Even in the face of globalization, marriage and childbearing within marriage continue as important features of social and personal life and son preference remains strong (Yeung and Hu, 2013). These features indicate that personal conduct and compliance with social norms are strong among Chinese young people (Nelson et al., 2004). However, there is evidence signifying a rise in the age of first marriage and childbearing, along with cohabitation and premarital sex in urban youth in modern China (Yeung and Hu, 2013).

Marriage is one facet of signifying transition to adulthood, but the acquisition of useful skills and employment are necessary for becoming economically self-sufficient and viable. This is addressed in the next section along with the role of instruction in socializing young people toward adulthood.

Skill Building and Learning

Apprenticeship

Apprenticeship is linked with learning and is a socially situated practice deriving importance and meaning as supported within the structure of the surrounding culture and society. Learning is a part of an ongoing, sometimes subtle, transition from unskilled to skilled workmanship (Lave and Wenger, 1991). For example, the Oku carvers in the Cameroon Grassfields utilize apprenticeships not only as a means of passing down knowledge of carving but also to shape the apprentice's new identity. The leaving ceremony that occurred in the past in Oku illustrates the conferral of adult status once the apprentice had learned all that he could from his master. At that point, the apprentice would bring an offering of food which the master would consume. This act served many functions including validation of the apprentice, celebration of the apprentice's success, and a marker of the apprentice's independence. Tools were traditionally limited to apprenticed carvers, who made the tools with the master gifting them to the apprentice for use in his own workshop. As tools became more available to non-apprenticed carvers, free market entrepreneurs emerged who carved and sold to dealers who then sold to foreigners and tourists (Argenti, 2002). In recent years, business with foreigner consumers has reduced, but the nonapprenticed Oku carvers continue to produce work. This dynamic suggests that carvers are not solely interested in pleasing the Western consumer but in creating a culture-based identity within the global political economy.

Informal Instruction

Universally, informal instruction is an implicit component of culture-based mechanisms for the transition to adulthood. For instance, puberty rituals were discussed in an earlier section but it is important to note that instruction of initiates is an integral component of many coming-of-age practices (Markstrom, 2008). The content of instruction includes socialization toward expected adult roles and responsibilities that frequently include gender-specific content. In Mozambique culture, informal instruction and counseling by community and family elders prepares the initiate for transition into a new phase of her life (Kotanyi and Krings-Ney, 2009). During initiation rituals, girls are taught about sexuality, moral adult behavior, feminine hygiene, traits of a good wife, and preparing the body for sexual activity. Female instruction during initiation rituals in Mozambique occurs in four stages over years with content specific to the age of the initiate ranging from a procedure of stretching the inner labia at ages 8–10 years to the birth of the first child (Kotanyi and Krings-Ney, 2009). A woman is said to be socially accepted as a complete individual after motherhood. These initiation rituals have also taken the form of HIV/AIDS education platforms in some of these communities as discussed earlier (Kang'ethe 2013). Informal instruction and counseling of this type can have far-reaching contributions providing an opportunity for women, particularly the integration of elderly women, into HIV/AIDS counseling (Kotanyi and Krings-Ney, 2009).

Similarly, in Malawi, informal instruction and counseling for young girls at the onset of their first menstruation is commonly practiced (Munthali and Zulu, 2007). An older woman serves as an authority on sexual and reproductive health and serves as the head counselor to young initiates. For boys, there is limited counseling on sexuality in some regions of Malawi because of the lack of characteristic markers of puberty such as menarche. Nonetheless, male relatives and friends instruct boys about sexuality (Munthali and Zulu,

2007). In other cultures, as well, for boys, the lack of a specific biological marker may account for the less prominent role of formal instruction and socialization toward adulthood – informal socialization may very well occur.

Discussion

This article has focused on culture-based practices facilitating the transition to adulthood in non-Western cultures with a particular eye toward our present-day global, interconnected, and changing world. Culture-based rituals can be sources of happiness, accomplishment, and build a sense of community among those that practice them, for whom rituals convey social capital (Kang'ethe, 2013). Globalization has brought with it a distinctive challenge to the youth around the world. It demands that they transform and reinvent traditional social markers while trying to maintain the embedded social capital that these rituals bring with them. Larson et al. (2009) categorizes societal changes in response to globalization as 'top-down' and 'bottom-up.' Top-down societal changes are driven by forces such as large corporations working in developing countries. The risk of such change is disruption of traditional subsistence economies and livelihoods, which may necessitate relocation to urban regions where cultural resources are absent. Bottom-up changes are driven by everyday people in a community or society who bring their resources to bear on the global community, such as marketing traditional wares of a culture to a broader consumer base. In response to bottom-up changes, youth often take on the role of 'social shifters' (Durham, 2000) and are active agents in processes of globalization. However, it is important to remember that the agencies and capacities of young adults across the globe must be contextualized in their unique social, demographic, economic, and political context. Customs may change more rapidly in urban and affluent settings where youth have more resources and economic mobility to be coconstructors of these new identities.

Given the fact that there is cross-cultural variability in the transition to adulthood (e.g., urban and rural distinctions as previously discussed), it is difficult to provide generalizing statements. However, the *Growing Up Global* project of the National Research Council attempted to define cross-cultural factors applicable in signifying success in this transition. They identified six factors:

- Good mental and physical health, including reproductive health, and the knowledge and means to sustain health during adulthood.
- An appropriate stock of human and social capital to enable an individual to be a productive adult member of society.
- The acquisition of prosocial values and the ability to contribute to the collective well-being as citizen and community participant.
- Adequate preparation for the assumption of adult social roles and obligations, including the roles of spouse or partner, parent, and household and family manager.
- The capability to make choices through the acquisition of a sense of self and a sense of personal competence.
- A sense of general well-being (NRCIM, 2005: p. 26).

Implicit to these statements are universal mandates that individual and societal maintenance require health, social capital, and prosocial values. Further, socialization of younger members of the society should include needed skills, values, and behaviors that contribute to self-, other-, and societal health and well-being.

In summary, the mechanisms and practices signifying the transition from adolescence to adulthood demonstrate cross-cultural variability as shown in this article. Some markers are biologically based (e.g., at pubescence) and these tend to occur earlier in adolescence, yet reflect societal perceptions that the individual is growing into adulthood and now should mirror more mature, responsible qualities. Other facets in the transition to adulthood encompass ceremonies and celebrations that may involve bodily modifications signifying adult status. Still other celebrations mimic the behaviors of adult such as dressing up in a more formalized manner, as in special formals, dances, or celebrations. Weddings are universal celebratory rites of passage in the transition to adulthood. However, in case of child marriage, such status is conferred prior to attaining the physical and socioemotional changes of adulthood. The final category of transition to adulthood delineated in this article encompasses formal and informal education and socialization of the young person for assumption of the roles and responsibilities of adulthood. Instruction may very well be a universal action associated with preparing youth for adulthood.

Translating Sociology into Japanese, Chinese and Korean Languages

Abstract

East Asia's encounters with the West include an interesting era of translation of sociological concepts into Japanese, Chinese, and Korean. This includes the concept of 'society' itself. This article explores how the concept of 'society' and sociology as a discipline were translated from European languages into East Asian languages in significantly different contexts to that of Europe. The authors focus on the role of intellectuals, organizations, and social movements in the process of development of Japanese, Chinese, and Korean vocabularies of sociology.

The intriguing history of East Asia's encounters with the West includes unusual cases of translation of sociology and sociological concepts into Japanese, Chinese, and Korean. This is simultaneously a regional process and three distinct (though connected) national processes associated with East Asian modernities. It is part of a phase of intercivilizational encounters of an exceptional kind.

East Asian Sociology: Western Modernity and Japanese Translation

Development of East Asian sociology is one of the civilization processes in which Western modernity was expanded to the far eastern region. In encounters with other civilizations, or the world religions or universal ideologies, Japanese intellectuals actively interpreted and relativized those civilizations, religions, and ideologies against a native cultural core. The Japanese case of translation of 'society' and 'sociology' is a case in point and an instructive case because of Japan's sudden encounter with Western sociology. 'Society' can be difficult to translate and would be doubly so with transliteration from one set of languages to another language family. Japan's acquisition of sociological concepts provides a rich case study in engagement with the unfamiliar in two respects. Firstly, the commitment to interpretation of Western sociology and the conceptual apparatus behind it produced a rapid change of understanding. Secondly, the change of understanding took place in a different language family and involved transliteration into kanji. That made the process of adaptation of sociology more complicated.

Meiji Japan's Engagement of Western Sociology

The young generation of converted samurai, which led the Meiji Restoration (1868) prioritized the acquisition and comprehension of Western sociology. The quest for knowledge stimulated the 1871 Iwakura Mission, an large-scale international tour of hundreds of Japan's leaders to the United States and much of Europe, a tour which must rate as one of the most systematic fact-finding missions in world history (Nish, 1998). The cultural learning that took place after nearly 400 days of travel incorporated many of the main disciplines in the physical and social sciences and humanities. Subsequently, the knowledge of engineering techniques, systems of government, and political philosophy and social science acquired was spread to a literate and intelligent populace. Within this wider engagement with global knowledge, three features of Western sociology attracted Japanese interest:

1. Comtean social thought encountered first by the Japanese appeared coherent and persuasive. Nishi Amane (1829–97) – a pivotal figure in early translation of sociological concepts – adapted it. He studied Comte in the Netherlands for 4 years in the 1860s. Comte's *Cours de philosophie positive* greatly impressed him and, like Comte, he introduced the term and idea of 'sociology' to the Japanese universe of learning. Comte's comprehensive and encyclopedic sociology provided one entire system of knowledge that could frame intercultural learning for the Japanese. The receptivity of the Meiji elite to the encyclopedic nature of the Western social sciences made Comte's evolutionary sequencing appealing in the 1870s.
2. For a new program of modernization, the Meiji elite needed an ideological vehicle. Comte's sociology – and succeeding it, Herbert Spencer's social evolutionism (Yamashita, 1984) – presented a theory of history, which validated the Meiji transformation and provided further cultural resources for it. The world-historical sweep of Spencerian and Comtean evolutionism was pliable enough to the climate of debate about the Meiji program of modernization (Nozomu, 1994: pp. 4–6). Ideologically, evolutionism made sense to a new regime striving to realize a place in the world order of empires. Comtean and Spencerian sociologies cast a world of modernizing states that were empire building, large-scale industrial capitalist economies.
3. Sociology as a body of thought presented itself as the science of social change, which was precisely the historical process that Japan was undergoing. As the transformation was led by a highly reflexive social force it had to involve an activist disposition toward the process of transformation itself. Sociology appeared to the Meiji elite to accommodate such a disposition. Learning and translating its conceptual apparatus became an urgent endeavor.

The translation and interpretation of social sciences associated with the project of 'civil society' separate from the state in a society that did not generate any such civil society was quite difficult. Even a word to connote the core concept of 'society' was hard to formulate.

Concepts in Translation

From the 1860s to the 80s, there were at least three Japanese words that could act as a translation of 'society': *nakama*, *setai*, and the part-neologism *shakai*.

Nakama (仲間) connotes a voluntarily instituted group of townspeople, in which members share a certain aim or belief and communicate as equals. Some were guildlike or corporate in nature. There were countless numbers of informal *nakama*, such as religious groups, hobby clubs, and alumni organizations. The Meiji intelligentsia experimented with the term *nakama* as an equivalent to 'society,' because it inferred qualities of civil society such as voluntary association and the institution of groups outside the range of kinship.

The second option, *setai* (世帯), has Buddhist origins and denotes the tacit norms of the earthly world. In the Buddhist world view invoked by *setai*, we have to obey tacit rules in ordinary life, even if we find them irrational and detestable. In contrast to a heavenly existence the mundane world appears a transient and provisional place (Sako, 2006: pp. 5–6). This phenomenological term for 'society' distinguishes the transcendental from the mundane. *Setai* is normative in effect as it implies tacit rules for ordinary life. On the occasion when sociology was taught for the first time at the University of Tokyo *setaigaku* was the translation for 'sociology' chosen.

Shakai (社 會) has the most telling history. Nishi Amane (西 周 1829–97) was the vital figure in the emergence of this term as the main one to translate 'society.' He operated in a rich intellectual milieu. Together with Arinori Mori (1847–89), Nishi founded the famous *Meirokusha* (明六社) publishing house and the journal *Meiroku Zasshi*. The *Meirokusha* ('Meiji Six Society') worked at the interstices of Western and Japanese perspectives on societal transformation. The work of the group's members couched the project of modern reconstruction in sociological terms for Japan (Braisted, 1976). They were translators also. Nakamura Masanao translated Smiles' *Self Help* and then Mill's *On Liberty*. Amane too was involved with translation of whole texts, including Mill's *Utilitarianism*. These translations and others presented touchstone works of Western thought to the Japanese. The thinking of the *Meirokusha* took place at the interstices of civilizational engagement laying out for the Japanese urban public "description of a received world and construction of a new one" (Howland, 2002: p. 5). They were not merely translators or conveyors of Western ideas. Their translations were an exercise in interpretative work that began the development of new sociological and philosophical ideas in Japan.

Translation across languages and language groups of key words featured in their early discussions. Nishi was the first to use the term *shakai* to denote 'society' in 1874. He translated 'philosophy' as *tetsugaku* and a number of other crucial terms. With *shakai*, Nishi intended to convey 'society' in the sense of 'associations' or rather 'societies.' Nishi's use is part neologism and part adaptation. *Shakai* was derived from twelfth to thirteenth-century Chinese literature and referred to "peasants festivals" (Sako, 2006: pp. 6–7). In Japan, *shakai* had a different use. In Nishi's hands, and in wider use by the *Meirokusha* and university authorities, *shakai* could be effective as a term for 'society.'

Despite its novelty, the careful recombination of *kanji* based on the Chinese original proved salient. Etymologically, the word *shakai* is compounded from *sha* (社, *she* in Chinese, *sa* in Korean) and *kai* (會, *hui* in Chinese, *hoe* in Korean). *Sha* (社) indicates shrine. *Kai* (會) denotes meeting or assembly. In Chinese, as noted, it signified 'festival.' The term *shakai* inherited by the Meiji intelligentsia carried the connotation of a meeting at a temple. The connotation of gathering in a public place of an open crowd was the closest equivalent to 'society' in the sense of constellation of 'associations' that Nishi was seeking. He was not alone in his use of this term. Spencer's work *Education: Intellectual, Moral, and Physical* was first translated in 1880 by Shinpachi Seki (尺振八). He used *shakai-gaku* for 'sociology.' Seki's translation was followed, in 1884, by Koutaro Noritake's (乗竹孝太郎) translation of Spencer's *Principle of Sociology* as *Shakai-gaku no genre* (社会学原理).

Nishi's role was more general than that of other Meiji intellectuals who specialized in large but particular problematics: the national spirit (Yukichi Fukuzawa), constitutional arrangements (Kato Hiroyuki), and the adoption of foreign customs (Tsuda Mamichi) (Motoyama et al., 1997: pp. 269–270). His intellectual authority helped consolidate recognition of *shakai* as the legitimate term in educational and government circles. *Shakai* and *shakai-gaku* had successfully emerged as translations of 'society' and 'sociology' in Japanese.

Chinese Development of Sociology

The idea of sociology entered the Chinese Empire in the 1890s, roughly two decades behind Japan. The rapid intake of Western knowledge caused a pressing need for Chinese translations of Western concepts. There were two approaches. The first, adopted mainly by reformists who were familiar with Chinese scholarship, was to create new phrases with characters carefully chosen to link the Western concepts with elements in Chinese heritage. The second was to borrow from the readily available stock of Japanese-made Chinese phrases. In many cases, there were parallel translations from an identical Western concept competing for recognition and acceptance (Huang, 2011). The term 'sociology,' too, had been associated with two Chinese terms. The first was *qunxue* (群學), a term that was related by its user to the classical Confucius doctrine. The second was *shehuixue* (社會學), a term of identical Chinese characters of *shakai-gaku* in Japanese.

Qunxue literally means the study (*xue* 學) of *qun* (群 or 羣), a character that consist of a figurative part meaning *sheep* (羊) and the phonetic part reads *jun* (君). Etymologically *qun* means 'sheep flock' or 'to drive sheep into flock.' It was later appropriated to refer to 'the action that leads to the formation of a group.' The Confucius philosopher Xunzi (荀子312–230 BC) wrote a paragraph that became widely cited in the elaboration *qun*. In *Wang Chi* (王制, literally 'king's institution'), an essay on the art of governance, Xunzi asked: why men, who 'are not

as strong as cow, nor can run as fast as horse,' could master the natural? The answer he suggested was 'the ability to *qun*.' He pointed out that this ability relied on 'division' (分) (of roles or resources); and division relied on *yi* (義, righteous and appropriate ethic). The 'division according to *yi*,' he argued, was the foundation for harmony, unity, and strength (Zhang, 1992: pp. 5–6). This 'ability to *qun*' became a central concern for many nineteenth-century Chinese intellectuals who attributed the series of defeat by the Western powers to the lack of national unity and cooperation (Yao, 2006: p. 19).

There is dispute on who first coined the term *qunxue*. Its first appearance in existing literature is in the 1895 article 'yuan qian' (原強, literally "original strength"), in which the author Yen Fu (嚴復), a renowned translator, illustrated the theories of Darwin and Spencer and translated sociology into *qunxue*. Yen Fu also translated Spencer's *The Study of Sociology* and published it under the title *Qunxue Yiyan* (群學肄言) in 1903. However, it was alleged by the political reformist Liang Q-Chao (梁啟超) that his mentor Kang You-Wei (康有為) had in 1891 included *qunxue* as a subject in the teaching curriculum of Changxing School (長興學舍) in Wanmu Cottage (萬木草堂), Guangzhou (Liang 1928). Some scholars accept the account while tracing the origin of *qunxue* (e.g., Zhang, 1992: p. 5), while others suggest that Liang might have borrowed the term from Yen's writing and labeled their earlier agenda as such (Chen, 1984; Yao, 2006: p. 24).

It is important to note that the version of *qunxue* described by Liang is of very different nature from Yen Fu's. The reformists' *qunxue* might have been inspired by Western ideas, but their understanding of Western sociology was superficial at the best and the project was largely a reinterpretation of Chinese classics (Yao, 2006: p. 24). By contrast, Yen employed the term *qunxue* only to connect the translated Spencerian sociology with the legacy of Xunzi. Yen's use of *qunxue* was imbued with Spencerian sociology.

Shehuixue, the alternative translation, was introduced in the aftermath of the First Sino-Japanese War (1894–95). The bitter defeats by the small Asian neighbor cast a huge impact. Eager to discover the secrets of Japan's rapid modernization, Chinese students started to flood into this Eastern neighbor to study a wide range of disciplines that include social sciences. Those students were exposed to Western scholarship through literature in Japanese language, which was linguistically more accessible to them than Western languages. Many started to introduce the modern sciences to China via introductory texts published on press, or even via translations of Japanese textbooks (Harrell, 1992).

This flow of modern knowledge inevitably caused the proliferation of "Japanese made Chinese language" (和製漢語) – the modern phrases translated by Japanese scholars (notably Nishi Amane) using Chinese characters. These imported phrases triggered strong criticism and resistance among the conservative elites in China, who considered those phrases a contamination of classical aesthetics of writing. Policies to ban their usage were seen in some schools or examinations. However, those imported phrases still grew in their popularity and continuously marginalized the translations coined by Chinese scholars. Four reasons are suggested. First, the inflow of modern knowledge was just explosive, highlighting gaps in Chinese language where the Japanese made phrases were the only communicable terminology. Second, even in places where a domestic translation existed, the texts translated from Japan just outnumbered and gave their terminology more popularity. Third, the translation coined by Chinese scholars generally showed a preference for classical aesthetics (e.g., fewer characters-per-phrase and links with Chinese classics), which restricted their acceptance among those who demand more comprehensible language. Fourth, Japan had already constructed a consistent system of terminology that makes its understanding more easily. By contrast, the translation efforts in China remain individual and fragmented (Huang, 2011).

The term *Shehuixue* first appeared in Chinese in 1896 when Tang Si-Tong (譚嗣同, 1865–98) listed *shehuixue* as the Western scholarship anyone devoted to *renxue* (仁學, "study of benevolence") should learn. He did not elaborate what *shehuixue* meant. Read in context, the term might be adopted to loosely refer to a general idea of "social studies" (Han, 1987: pp. 25–26). Ding Yi (1988) identified Han Tan-Shou as the first Chinese scholar who used *shehuixue* to translate sociology.

The systematic introduction of *shehuixue* into China started in 1902. Zhang Tai-yan (章太炎, 1869–1936), a philosopher and revolutionary in exile in Japan, published the first sociology textbook in China. This book was based on his translation of *Sociology* by Kishimoto Nomuta (岸本能武太). The translation of *Ethnic Evolutionism* by Ariga Nagao (有賀長雄) was published in the same year too. 1903 marked the publication of Wu Jian-Chang's (吳健長) translation of Giddings' *Theory of Socialisation* based on its Japanese translation by Ichikawa Genzu (市川源三) and Ma Jun-Wu's (馬君武) translation of Spencer's *The Introduction of Sociology* (Yen, 2004: p. 2).

Concepts of Society and Sociology in Korea

There were also early encounters between Koreans and Western sociology via Japanese translation. The earliest instance of translation of 'society' is found in 1896 when *sahoe* (사회) was first used as a newly translated version of *shakai* by Korean students sent to Japan by the government to learn 'civilization and enlightenment' (Park, 2000). The students formed the *Daejoseon Ilbon Yuhaksaeng Chinmokhoe* (Fraternal Society of Korean Students in Japan) and published the bulletin '*Chinmokhoe hoebo*.' In its second issue in March 1896, Sin Hae-yeong, vice-president of the society, and others wrote articles that utilized the term 'society.' The impact of this bulletin was limited but it took a relatively short time for the newly imported concept to become a commonly used word in Korea. By the early twentieth century, *sahoe* was in use in the articles of journalists and intellectuals educated in Japan.

As with Japanese adaptation of the conceptual apparatus of sociology, the process of translation was not a simple one-way expansion of Western thought, but a deep entanglement of Western, Japanese, and Korean conceptual universes. *Sahoe* was linguistically and conceptually different to *shakai*, even though both originated with the same Chinese characters as oral Korean was the real medium of communication in the Korean sphere of the public opinion not the written Chinese form understood in all three countries of East Asia.

This entanglement became more complex with Japan's colonization of Korea in 1910. The sharp divergence of spoken Japanese and Korean proved a flashpoint of conflict with colonial authorities. Koreans understood *sahoe* from the vantage point of their own semantic paradigm and experiences. Semantic independence could easily be mobilized as a cultural resource for political movement for national sovereignty. In order to suppress this sphere of independence, the Japanese colonizers tried to enforce the policy of using Japanese language in official life-provoking huge resistance.

By the 1920s, the notion of 'Korean society' (*Joseon Sahoe*) was in widespread usage. A number of conditions contributed to this enlarged meaning of society: emergence of a public sphere with consolidation of two famous vernacular daily newspapers, *Dong-A Ilbo* and *Chosun* Ilbo; an increase of scholarly and political debates in journals; the rapid growth of newly formed social organizations and social movements; and the increasing influence of socialism. Those conditions were all accepted as an interrelated phenomenon in that 'social' groups were engaged in a changing 'society,' which had to be analyzed by 'social' ideas. Socialism was translated into '*sahoe*-ism,' which was easily understood an ideology related with '*sahoe*.' Many collective movements both for national liberation and for class struggle were called '*sahoe*-movements.' The ideas and thoughts that supported these collective movements were named as '*sahoe*-thought.'

Under colonial rule, sociology generally served different and conflicting purposes. On one side, it was an instrument of Japanese colonial scholars who designed programs of sociological research to legitimatize colonial rule. Thus diverse research projects mapping Korean traditional folk culture, kinship structure, traditional organization, local markets, and religious life were carried out by scholars trained in sociology and anthropology. On the other side, the development of sociological knowledge and sociology's conceptual apparatus was utilized broadly by oppositional movements. Through this, sociology helped establish a terrain of conceptual tension, albeit within a tightly controlled public sphere.

The very meaning of 'society' was disputed. *Sahoe* carried three diverse connotations of 'society': a contract of independent individuals, the public character of social associations, and morality of integration. Developments in the late-nineteenth century created fertile conditions for the development of social contract theory. The abolition of traditional status estates in 1894 and rapid weakening of Confucianism provided a receptive environment for accepting the idea of individualism. The new concept of society was welcomed since it gave a chance to develop individuality against traditional conceptions of humanity. With the circulation of *sahoe*, a paradigm of three structures, 'individual-society-state,' came to be widely accepted. There was a plethora of essays written about the difference between state and society and the difference between individual and society. Society was regarded as a medium, buffer, linkage, and center between state and individual. It allowed imagination of a new space where independent individuals found their own position.

Another characteristic of *sahoe* was the legalization of voluntary establishment of associations and groups. This formalized an embryonic associationalism to which the concept of society could be applied. 'Society' suited the set of organizations that emerged. These applications in usages of the concept of society resulted in the dismantling of traditional corporate boundaries delimiting the public. Up until 1894 – when the social status system was abolished – the public was monopolized by the *yangban* class centering on the king, and any public authority or activities to criticize or refuse this monopoly were suppressed. Consolidation of the concept of society provided an occasion to understand a new public sphere that was different from the state and the ruling class. It was at this time that a word for public opinion was also introduced. *Yeoron* displaced the word of *kongron* (공론). Even though there were some disagreements regarding the effects of self-interest-oriented groups, the idea of 'the public' had changed as a result of increased interest and discussion about the idea of society.

A third important connotation of *sahoe* was a perspective that social community was an organic entity with moral solidarity. In textbooks strongly influenced by the governing Japanese, 'society' was explained in relation to the goal of moral consensus. This understanding of society as an organism carried a completely different implication from the social contract theory. In place of a tension between the social and the political, a general and fundamental institutional integration of individual, family, and state was emphasized. In this third connotation, 'society' was conceptualized with an uncritical set of depoliticized moral principles. Most Korean intellectuals could not accept that depoliticized notion of the public. Nationalists argued that public opinion had to be found within the people who had kept strong orientation to independence. For them, Korean society meant Korean national identity and hope. With increasing influence of socialism, intellectuals of the Left argued that society was a historical community characterized by class conflict, not by moral integration. In addition they argued that such struggle rather than moral harmony was the real driving force of historical development including socio-political independence.

During almost four decades of colonial rule, Japan tried to depoliticize the concept of society in colonial Korea, while Koreans continuously stressed the political implication of social elements for the national independence. It was not only a political conflict but also a cultural struggle for hegemony. The concept of society was freely used from the 1920s onward, but its meaning was not unitary, and its political implication also contained heterogeneous elements in many instances of its usage.

Conclusion

Taken as a whole, the circulation of translated sociological concepts at this time in East Asia can be seen as regional process made up of three separate (though linked) national episodes. As a case of intercivilizational encounters the translation of sociology and sociological concepts into Japanese, Chinese, and Korean is exceptional in that Western colonialism was not directly involved, though Japanese colonialism had a hand in Korea's case. East Asia has been a distinct site state of intercultural exchange in this period where the context of colonial power is different to other world regions.

Transnational Citizenship

Claus Leggewie, University of Giessen, Germany; and Kulturwissenschaftliches Institut (KWI), Institute for Advanced Study in the Humanities, Essen, Germany

Abstract

The article summarizes the growing literature on citizenship rules which have been conceived during the era of the nation-state and are now under pressure through transnational developments (globalization), by the multiple citizenship adherences within, for example, the European Union (EU), and through migratory as well as refugee movements of all kinds. Concepts to regularize these developments by multinational citizenship rights and/or a European citizenship as such are in debate. First attempts to institutionalize supranational citizen rights within the EU are discussed as approaches to a broader and more inclusive citizenship regime.

Citizenship: Legal and Cultural Dimensions

Citizenship can mean a lot of things, as described by Bauböck:

> 1. a *formal legal status* that links individuals to a state or another established polity (such as the European Union or a federal province); 2. a *bundle of legal rights and duties* associated with this status, including civil liberties, rights to democratic representation, and *social rights* to education, health care, and protection from poverty risks; 3. a *set of responsibilities, virtues, and practices* that support democratic self-government; 4. a *collective identity* that can be shared across distinctions of class, race, gender, religion, ethnic origin, or way of life.
>
> 2008: 3

Bauböck connects legal and political aspects of status and participation with cultural and identitarian phenomena that have always intermingled within the framework of modern nation-states (Bader, 1997; Fox, 2005). Indeed, various efforts were made to resolve the constant tension between the legal and the political features of citizenship and their cultural underpinnings via nation-building: some states were based on linking political status to ethnic descent, whereas most republics pretended to be 'culture blind.' However, immigration and transnational cultural interconnections have relativized these typologies, and economic and cultural globalization has definitely transcended the legal and political boundaries of sovereign nation-states.

Even before the formation of the modern nation-state, cosmopolitan aspirations were already emerging: *Me velle civis totius mundi non civis oppidi* was the answer of Erasmus of Rotterdam in the sixteenth century, when Swiss Reformation leader Ulrich Zwingli offered him citizenship in Zurich. The humanist philosopher is said to have replied that he did not want to become a citizen of a single city, but of the 'entire world.' World citizenship in this sense was always one of humanity's dreams, one considered as honorable as it was unfulfillable. Now globalization has not only razed the fortress of the nation-state (as progress in ballistics did the fortified walls of medieval city-states), it has also created the opportunity for what is called *transnational citizenship*. Historically, nations provided the framework of modern community and society; they defined (and limited) the space of communication within which political parties and interest groups of all kinds operated, thus creating the prerequisites for equal representation and civic participation. In the welfare state, too, who should be included in and who should be excluded from the system of mutual support was defined within this national framework. But the universalistic principle of inclusion itself helped migrants gain a highly valued status as residents, without being formal citizens. A person's national citizenship was thus uncoupled from his or her right to have rights, insofar as international laws, for example, to protect migrant labor, and human rights conventions became plausible as independent sources of individual and collective rights. The question at hand is: Between local patriotism and global markets, where is *homo politicus* located?

World Citizenship: Facets and Drivers of Transnationalization

The *Oxford Dictionary* dates the emergence of the term 'transnational' to about 1920, as documented by a quotation from an economic text that described Europe after World War I as being characterized by its 'international or more correctly transnational economy.' Interestingly, the dictionary provided another source identifying the Christian Church as the sole power that could create the conditions for a 'transnational, nonracial democratic polity.' One author, who had 'transnational America' in view as early as 1916, is not mentioned: Randolph S. Bourne. While the nations of Europe fought a savage war, this literary critic and pacifist from New York emphasized the special potential of the USA, something he thought could provide the bases for a future world society. The USA, as the 'first new nation' of immigrants, clearly did not have recourse to the European bases – either ethnic-cultural or state-bureaucratic – for nation-building and collective identity. On the other hand, Bourne rejected the then current idea of a 'melting pot': "We are all foreign-born abroad or the descendants of foreign-born, and if distinctions are to be made between us they should rightly be on some other ground than indigenousness." One should not seek the foundations of American collective identity in a mystified past, as was the case with European nationalism, instead "we must perpetrate the paradox that our American cultural tradition lies in the future." Bourne drew the conclusion, "America is coming to be, not a nationality but a trans-nationality, a weaving back and forth

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64014-X

with other lands, of many threads of all sizes and colors" (Bourne, 1916: 87, 92, 96).

At the beginning of the twenty-first century, 'transnational' has become a technical, but also a fashionable term. It is used especially in connection with international organizations and the 'multis' (transnational corporations). In accordance with the original meaning of the Latin prefix 'trans,' it points beyond the usual diplomatic dealings among sovereign nation-states and the customary division of labor among 'national economies'; the unit of analysis, not only in international relations, has become *Weltgesellschaft* (world society, see Luhmann, 2000). This did not imply the 'end of nation-states'; however, state sovereignty as we knew it has become 'anachronistic' (Czempiel, 1969). From the macroperspective or bird's-eye view of the world economy, the glance drifts to the microlevel of *Lebenswelt* (lifeworld), where we can trace the cross-boundary paths via which people and objects, metaphors and symbols, individual life histories, and collective biographies are transferred. It is time for social science and political actors to acknowledge this 'paradigm shift' from international to transnational relations, which is also to recognize that a new form of world politics is emerging: citizenship (and governance) beyond the nation-state.

Economic and Cultural Preconditions of Transnationality

From the beginning, the most powerful and conspicuous relativizers of the nation-state were the transnational corporations, with their world-spanning trade and finance transactions. There has been a world market since sailing and techniques of navigation first permitted intercontinental trade, currency exchange, and investment; the Hanseatic League or the spread of Chinese family households throughout the Pacific demonstrates that the postmodern subversion of national borders has its premodern precursors. Yet, capital's inherent 'lack of patriotism' (*Vaterlandslosigkeit*, Karl Marx) has meanwhile developed beyond the customary relations between parent companies and foreign subsidiaries; economic and financial conglomerates have merged so that, aside from having a legal seat, they are no longer anchored in one particular nation. E-commerce, including business-to-business deals, has further radicalized this despatialization.

Certainly, the prospects of the new economy must be viewed with caution, but state and cultural boundaries already play hardly their former rule in its leading branches – telecommunications, health care, and biotechnology. Elimination of boundaries through 'digital capitalism' already has dramatic consequences for taxes and customs – which, after all, are the primary sources of revenue for nation-states and even supranational economic communities like the European Union (EU). Global standards of management and services are joined by the harmonization of trade and economic law through legal firms, auditing companies, and consultancies. These need not really have global reaches; what we observe is rather a regionalization (in the sense of 'continentalization') of economic domains (North American Free Trade Association, EU, AEAN, Mercorsur, ECOWAS) or a geographic subdivision, as with the executive board of Internet Corporation for Assigned Names and Numbers and other transnational private–public institutions.

Migrant Communities

These examples show that transnational spaces have emerged since 1945. Operating in the interstices is a 'business class,' a loose conglomerate of managers, consultants, and service providers more closely associated with companies and concepts (e.g., the 'Apple culture' and the 'Linux movement') than with native countries and native tongues. Border-crossing mobility is not limited to the upper echelons of the labor market; even unskilled workers with precarious residence status have meanwhile become highly mobile and multicultural. This *Völkerwanderung* (mass migration), joined by masses of foreign travelers, commuters, and retirees in the Sunny South, has stimulated much thought about 'transnational social spaces' (Faist, 2000). Today's nomads differ from their long-familiar precursors, especially those caught up in the streams of immigration to the USA, Canada, Australia, and France in the nineteenth and early twentieth centuries. Today, 'homeland' and 'host country' are more closely connected and networks between them are much denser. With cheap transportation and easy communication, not to mention the worldwide reception of 'home' television and radio broadcasts via cable, satellite, and Internet, permanent settlement no longer seems necessary. Bags were always packed and ready in the Diaspora, but usually they remained in the attic; the back and forth of those times – for example, between New York's Lower East Side and southern Italy or between Chicago and Warsaw – also lacked the emotional routine that now characterizes transnational mobility, and above all it did not have the effects on the structure of entire societies that transnational communities are likely to have today (Ong, 1999; Schmidtke and Ozcurumez, 2007).

We can now define more precisely as transnational a social field, transcending national affiliation, in which a growing number of people lead a kind of double life. The expropriation of farmers, which tore the agrarian population from the 'soil' and drove them into the industrial cities, now finds its counterpart in a kind of 'expropriation of borders.' This casts doubt on sociology's 'container vision'; its spatial metaphors referring to closed national societies now seem outmoded. For many transmigrants live long term in two or more places, constantly speak two or more languages, possess *en masse* two or more passports, and pass continually in both directions through makeshift households, networks of relationships, and spaces of communication. From this perspective, migration 'routes' count more for cultural studies than the 'roots' of a migrant's personal identity in national collectivities (Clifford, 1997; Hannertz, 1996). All of which, perhaps combined with and crowned by the World Wide Web, a medium of transnationalization *par excellence*, leads to a despatialization that, unlike classic emigration, permits 'virtual proximity.' This allows communities to maintain themselves even without constant face-to-face encounters, as the poles – 'at home' and 'abroad' – of such transitory existence finally become almost interchangeable.

Religious Pluralism

Wanderers between the worlds generally bring their native gods and rites in their bags, for people who are supposed to have lost

their ties are especially likely to seek 'ties back.' The Latin of 'ties back' (*re-ligere*) is in fact the literal translation of 'religion.' Religious communities have always transcended national borders; spiritual belief is especially suitable for 'stretching' and reconstructing in what, following the scattering of Jewish and early Christian congregations, became known as 'the Diaspora.' While the supralocal spread of religious ideas and communities is not new in principle (the Catholic Church can be seen as the first ever agent of globalization during the Roman Empire in the Mediterranean world), the transnationalization of religion is no longer identical to Christianization, nor has secularization, which became typical for the Christian societies of Europe, prevailed as a global model.

Though religious life, along with the dominant cultures based on it, is relativized by transnational migration, emigration can revive religious feelings of belonging. In regard to world society, religion pushes globalization forward precisely by resisting the profane effects of economic globalization and forming particularist congregations. Diaspora, once experienced as catastrophic, is no longer an exception in the religious pluralism of our time; at the same time, protection of religious freedom has improved all over the world, so that imported religious symbols are becoming visible again in the public space of secularized societies. Globalization is thus not limited to corporate mergers, Internet communication, and financial transactions. Religious communities, too, travel around the globe, and not only with the organizational and functional support of world churches, but also and especially as decentralized grassroots movements, as an unofficial, heterodox, self-founding, religious civil society.

Hybrid Popular Mass Cultures

That which can be said about religious coexistence is also true for the diffusion and mixing of multicultural societies in general. A characteristic of this world of hyphens is provided by 'world music' (e.g., in the work of Peter Gabriel or the Putumayo label) – a collage of disparate materials that often fuses completely contrary styles. In such mixtures, which are described as 'hybrid' in allusion to biological crosses, things grow together that would not sound compatible to any purist's ear. But proponents of musical and other cultural mixtures point to more or less successful combinations dating all the way back to the origins of art. Indeed, on the whole, the creativity of cultures is never based on keeping the foreign at a distance. Rather, it is based on 'extraordinary' borrowings, on mimetic appropriation and the constant exchange of inventions, on innovation at the margins, and on the acquisition of the seemingly unassimilable. Seen in this way, phenomena of 'world culture' merely signal a further stage in the hybridization of hybrid cultures. All efforts toward canonical restoration are futile and the barriers between high and low culture have been razed too (Appadurai, 1996; Tomlinson, 1999).

The 'wild' combining of artifacts, symbols, and identities began as the primary means of expression and communication; language itself underwent 'creolization' at the points of contact between two or more groups of speakers. The process of assimilation was usually asymmetrical and often violent, but, at the same time, hybrid constellations mirror the growing interdependence of world society, which of course excludes as often as it includes. In this process, components of all cultures are uncoupled from local roots and contexts; this has often been interpreted as 'standardization' and, since the origins of hegemonial popular culture can often be traced to the United States, as Americanization. There is much to be said for this assumption, if we observe the selectivity and modes of influence of the culture industry, the effects of which sometimes amount to a kind of cultural extinction; on the other hand, fulfilling the world society's structural demands does not lead to complete cultural uniformity.

In the terminology of cultural anthropology, culture must be conceived as bounded and embedded, and thus as a field that can be cultivated only in a particular time and place. The global economy and technology require and produce universal phenomena like money and standardized systems of experts, which are of necessity oblivious to local origins. Abstraction is the only thing that permits communication and creates trust. And although cultural enclaves do resist standardization, it is now rare for this aloofness to achieve the power of a fundamentalist resistance aimed at preserving one's own culture. For however much desires for distinctions can be agitated and pitted against each other in the 'culture wars,' in the end, they remain oriented toward a structure of common differences. Popular mass culture permits travel through time and space without requiring viewers and listeners to leave their homes. For the first time, 'major events' – including warlike conflicts, athletic competitions, and appearances by entertainment stars – reach global audiences via electronic mass media such as CNN and MTV. There are topics that enthrall literally the entire world, and there are growing audiences for global stagings. But this thematic concentration is accompanied by a fragmentation of local audiences, which again illustrates the dialectics of globalization and localization. Social media are the latest proof of this glocalization of communication.

Transnational Citizenship: Two Challenges of Constructing a Demos beyond Borders

These tendencies have all relativized the traditional concept of citizenship as being bound to the entitlements and duties determined by a nation-state. If the nation, in combination with government (incorporating the mechanisms of bureaucratic agencies and popular representation), has been the fulcrum of personal identity and the condition for social affiliation and membership since the nineteenth century, at the beginning of the twenty-first century, flexible forms of belonging and community transcending the nation-state challenge the representivity and legitimation of democratic rule. Now the question is: Between local cultures and global markets, how can a cross-border demos be constructed?

Transnationalization of Citizenship via Migration

Emigration and immigration have been the main causes of a growing incongruence between cultural and political collective identities: Emigrants from country A turned their back to their former homeland and forged new affinities in country B even if many of them retained some emotional ties to their country of origin (A) and tended to assimilate to their

country of choice (B) via compatriot communities from country A. The same is true for immigrants: While they centered their lives on a new location (B) they retained more or less strong loyalties to their 'heimat' (A), sending money home and keeping up-to-date on what was going on there while continuing to speak their mother tongue (van Bochove et al., 2010; Kaya, 2012).

As already mentioned, cheap airfares, mass-produced communication devices with a global reach, and personal contacts via social media have further relativized the dichotomy between country A and B; transnational communities have emerged in the lifeworld. Thus, expatriates may want to participate in the political life of their former homeland and may even be inclined to vote in their former constituencies or as a particular voting bloc of nonresident citizens from abroad, and immigrants may stipulate voting and other participatory rights to overcome their status as noncitizen residents (Bauböck, 2005; Lopez-Guerra, 2005; Rubio-Marín, 2006; Owen, 2011). As immigrants here (A) are expatriates there (B), they might even have the idea of being a part of two 'demoi' and contributing to the political agenda of two states. It was exactly this prospect that conjured up the evil of 'illoyality' in the minds of the administrative agencies in the Westphalian system of distinct and incongruous nation-states (Benhabib, 2006; Schmidtke and Ozcurumez, 2007).

Nevertheless, nation-states and political elites have allowed not only for the electoral inclusion of citizens living abroad (which is supported by ethnic conceptions of nationhood beyond a territorial state), but also for electoral rights of noncitizen residents. One reason is the desirability of the political integration of immigrants, underpinned by civil and social rights; other explanations can be drawn from historical links (e.g., a common, immemorial past, the Commonwealth, etc.), cultural affinities, and linguistic community. Bauböck (2005) has sketched four ideal-typical positions speaking for or against this undermining of traditional concepts of national citizenship:

1. Civic republicans would argue that "only citizens who are present in the polity can govern themselves by participating in making laws" (685); a republic may be open to newcomers but those should apply for full citizen rights by naturalization and giving up former citizenship(s).
2. Ethnic nationalists would "support the inclusion of expatriates but reject political rights for noncitizen residents" because they conceive the nation as a community of culture.
3. Liberal democrats would, on the contrary, hold that voting rights for expatriates might undermine "the integrity of the democratic process since those who live permanently abroad should not be able to influence the making of laws to which only internal residents will be subjected" (686, see also Lopez-Guerra, 2005); however, they would favor voting rights for noncitizens just because long-term residents are effectively subjected to the local political authority and its laws, so noncitizens should therefore have "equal rights to representation and participation in the making of these laws" (686).
4. Cosmopolitans would claim for voting rights and participation on the grounds of an all-affected principle: *quod omnes tangit ab omnibus approbetur* (what concerns all must be approved by all). In this case, the demos is not a given entity of people but is constructed by way of those decisions that have a "profound impact on the interests of another country's population" (686).

As one can object to all the four concepts, Bauböck introduces a fifth principle he calls 'stakeholder citizenship' (2008). This involves a mixture of republican and liberal cosmopolitan principles. With regard to the former, it retains the idea that citizenship guarantees the status of full membership in a self-governing polity and that voting rights should generally be attached to such status. In accordance with liberal cosmopolitan principles, stakeholder citizenship would give stakeholders a subjective claim to membership and electoral rights. Bauböck provides a balanced conclusion: "Stakeholdership should … be less vague and overinclusive than affected interests. […] [It] would require the political inclusion of immigrants, but – different from inclusion derived from mere territorial subjection – it could justify the condition of long-term residence and the common requirement that immigrants have to apply for naturalization instead of being automatically turned into citizens. Stakeholdership would also permit (although probably not require) extending the vote to expatriates, but it would exclude those who have never lived in the country and would not give access to citizenship to persons whose interests lie in economic investment or tax evasion but who do not take up permanent residence" (2005: 686).

Transnationalization of Citizenship via Stakeholdership and Participation

Emigration and immigration have given rise to a revision of common understandings of how a people is constituted and what democracy as rule of the people means. The literature distinguishes two principles – the all-subjected principle, where the guiding idea is "that those subject to a rule also should be its authors"; and the aforementioned all-affected principle "that all those affected by a political decision ought, directly or indirectly, to have a say in its making" (Näsström, 2011: 120, 117). The first rule starts from a given people, be it the (very exclusive) demos of the Greek polis or the (more inclusive) demos of a modern republic. The second rule shifts the focus from a given people within polis and nation-state boundaries to (the justifying of) people-making within a democracy whose political agenda becomes transnational as well as transcultural. This does not only mean that "the demos needs to extend to everyone in a particular territory" (Gould, 2006: 49) but also enlarges the citizenry beyond the city walls and state borders. The all-affected principle negotiates and politicizes the boundaries of decision making.

With regard to the watering down of national sovereignties, all citizenship regulations tend to be conservative and exclusive, and the naturalization processes within most states continue to remain rigid and dismissive. As already shown, mass immigration has put the accepted status of national citizenship in doubt and the number of people with multiple citizenships in Europe has seen considerable growth. This growth in the possession of more than one nationality is, however, viewed with suspicion by many states, as they still believe it to promote conflicts of loyalty. The children of immigrants are, therefore, often forced as adults to decide

between their cultural and geographical origins. For example, second generation Turkish settlers in Germany will be made to decide between becoming Turkish or German; a decision which could then ultimately lead to a loss of their EU citizenship. Something which of course does not happen in families of mixed European citizenship, where, should the offspring decide to become French, Dutch, German, or British, they would nonetheless retain their EU citizenship.

Nevertheless, the national monopoly on citizenship is gradually beginning to weaken. A great many practical and normative arguments exist for the granting of transnational citizenships and the development of voting rights for foreign nationals. The economic and cultural impacts of globalization are, for example, gradually creating scenarios, where, within many areas, long-term foreigners are able to claim a greater say in what goes on around them. Meanwhile, in law scholarship and within the social sciences, the term 'global rights' is gaining in influence. Global rights are rights granted to people independent of their locations and are supported by wide-ranging human rights standards. Some of these standards themselves contradict national laws, and yet their impacts can, as in the case of the German Asylum Reform of 1992, often only be reduced through procedural limitations.

Such international developments suggest that reforms of the state citizenship regime are overdue and that these reforms should lead to more inclusive and flexible judicial statuses for people worldwide. Bauböck has repeatedly proposed the 'stakeholder principle' as a broader successor concept to the idea of citizenship: "Stakeholders are those who have a stake in the polity's future because of the circumstances of their lives." The so-called 'all-affected principle' goes a step further. It suggests that we can all be affected by global catastrophes and that therefore, we are indeed all 'all affected.' And if the role of nature as protagonist can be recognized in this sense, then why not also consider the proposal, that, not only humans but also nonhuman sentients and other objects or phenomena should be formed into a 'parliament of the things' (Latour)? Furthermore, where the rights of future generations play a role in contemporary decision making, there has been debate regarding the consideration of specific voting rights for children, to be exercised *in absentia* by their parents (Goerres and Thieman, 2009).

One note on spatial inclusion: Suppose we take the term 'global society' as being not just a metaphor (as do the majority of sociologists), but a reality forged by communications, transport, and free exchange within a globalized social sphere. It can then be argued that the space within which to exclude someone consequently ceases to exist and that societal exclusions become completely unjustifiable (Stichweh, 1997). Stichweh came to the conclusion that exclusions nowadays are only internal and temporary and that a dynamic exists, within which an act of inclusion occurs with every (attempted) act of exclusion. This is best displayed in total institutions. For example, in a jail, criminals are taken out of the society within which they would normally exist, yet in most circumstances this occurs with the explicit aim of then ensuring their ultimate reintegration into the society from which they have temporarily been removed.

Another note on generational inclusion: The potential heteronomy of future generations will ultimately be determined by their own future circumstances. People today simply cannot judge what coming generations will do and are equally unable to preordain what they themselves should do or allow to be done to them. The concept of sustainability (and indeed that of budget balancing as recently framed within the fiscal pact in many OEEC states) has, however, inaugurated an important proviso. Namely, it is advisable for people living within a dynamic, growing, global society to not only not use more of their resources than can then be realistically regenerated, but also abstain from impinging so much upon future generations, that dangerous, existence-threatening tipping points are both reached and surpassed.

A graphic example of unacceptable levels of heteronomy for future peer groups is the program for the 'temporary' storage of atomic waste, an issue for most EU member states. As part of this program, waste is temporarily placed in a location while its final resting place is discussed. These discussions, however, tend to last at least two generations, despite the fact that the radioactive outfall from this temporary placement can have a lasting impact upon an area for thousands of years. In this example, the temporal and spatial elements of concern are therefore united, as the risks of atomic energy hardly allow themselves to be confined to either national territories or specific periods of time. Right now, numerous atomic waste shipments are traveling across national boundaries throughout Europe. An international supervisory commission, however, only exists in the most rudimentary of forms and this despite the fact that a recent EU Commission report stated that the majority of European reactors are insufficiently secured. This example illustrates how political stakeholders can be on the receiving end of international decisions, regardless of state and/or cultural boundaries (Mason, 2009; Bauböck, 2009b; Owen, 2011).

It would, however, likely be difficult to reconcile stakeholder citizenship with the present system of state citizenship. 'Cultural' grounds will doubtless be raised. By which I mean the ethnic and religious differences between nations, which, from a traditionalist perspective, often preclude supranational integration. It is said, for example, that supranational bodies pay too little attention to the respective particularities of individual groups (such reasoning is presently being used by various groups in Spain, Belgium, and Scotland to demand greater regional independence from the central governments in these countries). Naturally, such objections tend to ignore the binding relationships between various peoples across national borders. Historically, these cross-border affinities have, in fact, been strongly emphasized, and never more so than in postwar societies where long-standing enmities are gradually reduced through transcultural exchanges and political cooperation. An exemplary model for this can be seen in the case of Germany and France, while moves are also being made in this direction in, for example, the ethnic and religious communities of the countries of the former Yugoslavia.

Prospects of Supranational Citizenship: The Case of the EU

The challenge then is to develop a concept of citizenship that is wide enough to address the ways in which national citizens are affected by global problems of all kinds (e.g., climate change) and concrete enough to represent the identitarian and communitarian bases of being a citizen in the context of

a particular *Lebenswelt*. The EU, until now, provides only a rather embryonic form of citizenship, limited to a formal legal status. The existence or even possibility of a European demos is disputed and contested. An EU citizenship per se does not yet exist as the individual EU states continue to defend their right to give and take citizenship as a national privilege. Behind this fiercely defended national right lurk the ancient, never fully applied, and increasingly undermined myths of the national union of land, culture, and ethnology. Whether German, Polish, or French, citizenship is determined either through birth or through a demanding process of naturalization. In the case of official national identity, it would appear that there is, as yet, no third way.

For the success of such supranational ventures, high levels of empathy and well-thought-out routines for cooperation are prerequisite, as well as the ability and desire to understand your counterparts. What is, however, uncertain is whether a transnational citizenship then subsequently develops out of such a process, bestowing the citizens concerned with institutionally secured and enforceable rights and duties. In other words, rights that are not just morally demanded but are also successfully exercised. A citizen of the EU is, according to Article 20 of the treaty on the functioning of the EU, an individual who possesses the nationality of an EU member state. Citizenship of the EU is therefore an extension, rather than a replacement, of national citizenship. European citizenship rights include the right to appeal to EU representatives, to instigate new legal proposals, and to participate, both actively and passively, in elections relating to the various European institutions. Additional rights bestowed upon European citizens include the freedom of movement within and between EU territories and certain residential rights for both them and their dependents. These residential rights have also been streamlined in order to reduce to a minimum the administrative effort involved in establishing one's entitlement to them. Limitations have also been placed on the circumstances within which these rights can be refused. In fact, every citizen of an EU nation has the right to permanent residency within any other EU state so long as he or she has spent at least 5 years uninterrupted within the said state's territory without committing any offenses for which action has had to be taken against him or her. This right comes without further requirements and also applies to any familial dependents of the individual concerned – regardless of their own nationality – so far as they themselves have also spent 5 years uninterrupted within a member state. Both EU citizens and their dependents also have a right to the diplomatic and consular services of all EU member states when in a country not of the EU.

How then would the application of a regional 'all-affected' principle build upon the status quo? As regards a statement of transnational citizenship, the participational rights of residents within EU states could be improved upon by adopting the proposals suggested at the Arhus Convention: for example, enabling citizens to participate in national votes, citizen initiatives, or class actions (Wallrabenstein, 2012).

The following European programs are already in place to promote similar initiatives and should lead to changes in this direction:

- Council Decision 2010/37/EC of 27 November 2009 on the European Year of Voluntary Activities Promoting Active Citizenship (2011) aimed at creating conditions that enhance the *participation of civil society in voluntary activities*, as well as increasing the visibility of volunteering.
- Council Decision 2007/252/EC of 19 April 2007 has established for the period 2007–13 the programme 'Fundamental Rights and Citizenship' as part of the General Programme 'Fundamental Rights and Justice'; it aims to promote the *development of a European society based on respect for fundamental rights*, to strengthen civil society and encourage an open and transparent dialogue, to fight racism and xenophobia, and to improve mutual understanding between the judicial and administrative authorities and the legal professions.
- Decision No 1904/2006/EC of the European Parliament and of the Council of 12 December 2006 established for the period 2007–13 the programme 'Europe for Citizens' to promote active European citizenship; it may create the *preconditions for a European demos by developing a European identity among European citizens* based on recognized common values, history, and culture, and by fostering a sense of ownership of the EU among its citizens.

More concrete was the Charter of Fundamental Rights that recognizes a range of personal, civil, political, economic, and social rights of EU citizens and residents, enshrining them into EU law. It is grouped into six major fields which I would like to quote extensively because they are almost unknown to the most European citizens:

Chapter I: *dignity* (human dignity, the right to life, the right to the integrity of the person, prohibition of torture and inhuman or degrading treatment or punishment, prohibition of slavery and forced labour);

Chapter II: *freedoms* (the right to liberty and security, respect for private and family life, protection of personal data, the right to marry and found a family, freedom of thought, conscience and religion, freedom of expression and information, freedom of assembly and association, freedom of the arts and sciences, the right to education, freedom to choose an occupation and the right to engage in work, freedom to conduct a business, the right to property, the right to asylum, protection in the event of removal, expulsion or extradition);

Chapter III: *equality* (equality before the law, non-discrimination, cultural, religious and linguistic diversity, equality between men and women, the rights of the child, the rights of the elderly, integration of persons with disabilities);

Chapter IV: *solidarity* (workers' right to information and consultation within the undertaking, the right of collective bargaining and action, the right of access to placement services, protection in the event of unjustified dismissal, fair and just working conditions, prohibition of child labour and protection of young people at work, family and professional life, social security and social assistance, health care, access to services of general economic interest, environmental protection, consumer protection);

Chapter V: *citizens' rights* (the right to vote and stand as a candidate at elections to the European Parliament and at municipal elections, the right to good administration, the

right of access to documents, European Ombudsman, the right to petition, freedom of movement and residence, diplomatic and consular protection);

Chapter VI: *justice* (the right to an effective remedy and a fair trial, presumption of innocence and the right of defence, principles of legality and proportionality of criminal offences and penalties, the right not to be tried or punished twice in criminal proceedings for the same criminal offence).

Since 1995, the European Ombudsman, on behalf of Europe's citizens, has been investigating cases of alleged maladministration by EU institutions or bodies, that is, the European Commission, the Council of the European Union, the European Parliament, etc. The EU citizenship report of 27 October 2010 'Dismantling the obstacles to EU citizens' rights' (COM (2010) 603 final) has identified the main obstacles that EU citizens may still confront in their private, academic, or professional life, when consuming goods and services or in their role as political actors.

Conclusions

1. There is a continuous tension between (inclusionary) citizenship and (exclusionary) cultural identity. By means of exclusion, ethnonationalism wishes to resolve this tension in a destructive and often militant fashion. As a result of its cultural blindness, republicanism dispels the tension by ignoring it. In most cases, the behavior of transmigrants who have created truly transcultural spaces must not be mistrusted by state authorities at all. They predominantly identify with the local community of their compatriots and with the wider urban community as well as with families and relatives at home – to whom they pay visits, make phone calls, and eventually send remittances. However, they rarely maintain 'thick' political loyalties relating to their country of origin. This is the case in ties to the home country based on political religions, for example, of communities from India and Pakistan. Localism and transnationalism challenge the perceptions of the established domestic populations only insofar as their ethnic and/or religious identities are concerned.
2. Global communication and cultural industries, transnational migration, and international market relations have led to the relativization of state borders, rendering purely national affiliations a fiction, and paving the way for a significant number of instances of dual or multiple nationalities. Awarding dual and multiple citizenships irrespective of cultural, ethnic, and religious background should therefore be seen as a more effective integration tool than assimilationist policies that operate on a legal level.
3. Global problems, such as climate change or other environmental risks, the crisis of financial markets, and the abuse of human rights, have led to the political demands of participation extending beyond nation-state borders and the opening up of a cosmopolitan arena beyond the nation-state and the United Nations system. Being 'all affected' is not sufficient in and of itself to guarantee effective participation; the stakeholder principle must be supported by effective citizenship rights (voting, access to the public sphere, recognition of NGOs, etc.).
4. The EU serves as an advanced example of an institution that provides a basis for supranational citizenship. Even though the EU is the result of national citizenship, it is 'overdetermined' by numerous cosmopolitan elements. Through supranational legal title, rights of participation of a moral nature are secure and can be effectively exercised. The EU thus provides a replicable model of a regional union that supports supranational citizenship.

Transnational Organized Crime

Toine Spapens, Tilburg University, Tilburg, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Even in history, criminals crossed borders to commit crimes, traffic in illicit goods, and provide illegal services. More recently, however, opportunities for transnational (organized) crime have increased, in particular because of the growing level of mobility, the opening of borders and the advent of the Internet. So far, however, there is little proof of the emergence of 'crime multinationals.' Although a complex and growing legal and organizational framework is in place, law enforcement cooperation is still largely traditional and it remains advantageous for criminals to operate across different jurisdictions.

Introduction

This article focuses on transnational (organized) crime and the instruments developed by the international community to combat it. The fact that criminals cross the borders of jurisdictions to commit crimes, avoid arrest and conviction, and traffic in illegal goods is of course nothing new. Section Transnational Crime in History: Some Examples begins by addressing some historical examples of transnational crime. In recent decades, however, cross-border crime has expanded and diversified, in particular because of the increasing level of mobility, the opening of borders and the emergence of the Internet. Section Developments in Transnational Crime since World War II discusses these developments. Next, Section Transnational Crime Networks focuses on whether some crime syndicates, such as the Italian Mafia and the Chinese Triads, are developing into crime multinationals that span the world. The subsequent sections address how law enforcement agencies from different countries cooperate in the fight against transnational (organized) crime. Section The Legal Framework discusses the development of legal frameworks, such as the bilateral and multilateral conventions necessary for law enforcement cooperation. Section The Organizational Framework then describes the institutions, such as Interpol, that play an important part in law enforcement cooperation. Section Conclusion concludes this brief overview.

Transnational Crime in History: Some Examples

Transnational crime is in itself not a new phenomenon and there are many historical examples of criminals crossing the borders of jurisdictions to commit crimes, traffic in illegal goods and offer outlawed services such as prostitution. Banditry, for example, flourished in Europe from the seventeenth to the early nineteenth centuries. Bands of brigands committed crimes in Northwestern Europe, in the Balkans, the United Kingdom, Italy, and France (Hobsbawm, 1972; Chesney, 1979; Henry, 1984). Although some of these groups limited their activities to the local level, others were highly mobile and operated across different jurisdictions. A Dutch example is the White Feather gang. Its members resided in Kaatsheuvel in the south of the country and totaled almost a 100 members, including women and children (Grootswagers, 1983). Such gangs committed burglaries and violent robberies in the countryside and extorted money from farmers by threatening to set fire to their farmhouses unless they paid them off (Egmond, 2004). Dutch gangs also operated in what is now Belgium and in the German border areas. Their demise finally came after 1798, when the government, under French influence, introduced a unified penal code that put an end to the independent powers of several 100 local jurisdictions. Furthermore, the State assembled Gendarmerie units to operate in the countryside. In only a few short years, the gangs were history. New opportunities arose for criminals in the Netherlands when Belgium gained its independence in 1830 and it became lucrative to smuggle all sorts of goods back and forth across the new border. One of the hamlets that had once been the lair of an itinerant gang was located close to the new border, and it rapidly turned into a notorious smugglers' den. Large-scale smuggling continued until 1960, when the Benelux Customs Union came into effect (Spapens, 2012a).

Another interesting example is the international trafficking in women, which was acknowledged as a growing problem at the end of the nineteenth century. The problem of 'white slave traffic,' however, must be viewed in a broader context. From the eighteenth century onward, the Industrial Revolution brought about fundamental changes in the lives of Europeans and North Americans and sparked rapid urbanization. The social disorganization and poverty in the cities promoted large-scale alcohol abuse, prostitution, and gambling. One of the responses was a revival of moral values from the second half of the nineteenth century onward, known as 'Victorianism.' Starting in the United Kingdom, the battle against alcohol, prostitution, and gambling spread to other countries.

In the late nineteenth and early twentieth centuries, large numbers of women began to migrate to other countries for shorter or longer periods to work, for example, as servants for well-to-do families. The debate about moral values, combined with this migration (which occurred across Europe), triggered the discussion concerning white slavery (Doezema, 1999). Scholars now believe that the actual number of trafficking cases was very small, although the problem did exist, notably in connection with sexual exploitation. In Europe, white slavery was discussed at a conference organized in Paris in 1895, followed by similar conferences in London and

Budapest in 1899. It led to the International Agreement for the Suppression of the 'White Slave Traffic,' signed in Paris in 1904, in which 13 countries agreed to take measures to protect women and girls effectively against this type of crime.

In the course of the nineteenth century, the need for international cooperation in the field of cross-border crime and terrorism also increased (Fijnaut, 2010). In 1898, a number of European countries convened in Rome and agreed to join forces to combat violent anarchism (Bach Jensen, 1981). This meeting was followed by a symposium in Monaco in 1914 on how to tackle cross-border crime. After the First World War, other types of transnational crime appeared on the international agenda. In the 1920s, for example, inflation was endemic in Germany and led to the counterfeiting of money, particularly of hard currencies. Another emerging type of crime was the trafficking in stolen vehicles.

These developments in turn triggered the founding of the International Criminal Police Organization – Interpol – in Vienna in 1923. The Nazification of Interpol by the Third Reich brought the organization into disrepute, among other things because information on the Nazi's political opponents stored in its records fell into the hands of the regime. However, the need for an organization for cross-border police cooperation was evident and led to Interpol's reestablishment in as early as 1946 (Bresler, 1992).

Developments in Transnational Crime since World War II

After the Second World War, the opportunities for committing crimes across borders increased. First, from the 1960s onward, the demand for illicit drugs grew and became more diversified. Second, the fall of the Iron Curtain in 1989 created new markets for European criminals, and the 'open borders' of the Schengen zone in Europe not only made it easier for them to move around but also sparked the phenomenon of cross-border petty crime in border areas (Spapens, 2010a). Third, the steady increase in mobility had profound effects on the nature and scope of transnational organized crime. Finally, new types of cross-border crime developed along with advances in information and communication technology, such as cybercrime, but also because environmental crime emerged as a new category of crime, for example. Below, these developments are discussed in more detail.

Youth culture developed rapidly in Western countries in the 1950s and 1960s. Part of this trend was the increasing use of illicit drugs, particularly hashish and marijuana. Users and dealers in colder climates had to import the drugs from abroad, and Pakistan, Lebanon and Morocco soon became important source countries for European users. At first, the drugs were smuggled in small quantities by young people, often users themselves, who had traveled to the East. As demand increased, traditional criminals also started to discover the market, and some of the 'hippies' managed to expand their businesses as well. Demand for other types of illicit drugs, such as heroin and cocaine, increased in the 1970s and 1980s, and in the 1990s ecstasy became fashionable among large numbers of users.

The global drug market gradually expanded and now involves a considerable number of people. The United Nations Office on Drugs and Crime estimates the number of people who have used illicit drugs at least once in 2010 at about 153–300 million worldwide (UNODC, 2012). Most of these used cannabis (119–224 million), followed by synthetic drugs (14–53 million), opiates (13–21 million), and cocaine (13–20 million). About 60% of all drug users live in Asia. Heroin, cocaine, and synthetic drug production is concentrated in a relatively small number of countries, and the products must usually be trafficked over long distances to reach customers. Afghanistan is the source country of most of the poppies used to manufacture heroin. Colombia and Peru are the main producers of cocaine. Important producers of synthetic drugs are Myanmar and the United States for methamphetamine, Canada, the Netherlands, and Belgium for ecstasy, and the latter two along with the Baltic States for amphetamine (Paoli et al., 2010). By comparison, cannabis cultivation is far more widespread, particularly since the introduction of indoor cultivation methods in the early 1990s. This implies that smuggling lines for hashish and cannabis are relatively short.

It is clear that the intricate distribution network for illicit drugs involves thousands of persons in different roles. Of course, not all members of this network are globally connected. Instead, the network is 'glocal' and composed of local subnetworks of producers and consumers, linked by traders (Hobbs, 1998). There are people who grow cannabis, poppies, and coca leaves, for example, groups that manufacture cocaine, heroin, and synthetic drugs, and sell them to wholesalers, who export from several hundred up to several thousand of kilos of illicit drugs. Of course, there are also small entrepreneurs who smuggle kilos or even less. At the end of the distribution chain, we find the small dealers who are in direct contact with the customers.

The fall of the Iron Curtain in 1989, followed by the disintegration of the former Soviet Union, are the next events important for the development of transnational crime. The opening up of the former Warsaw Pact countries created new crime markets. Demand for illicit drugs increased in the East, and new smuggling routes emerged, for instance for heroin via Tajikistan to Russia (Paoli et al., 2010). In the former communist world, demand for luxury goods rose, for example, for Western-built cars. Itinerant crime groups emerged, some of whom specialized in stealing vehicles and vehicle parts in Western Europe to sell at home. Other groups, for instance originating from Southeastern Europe, temporarily based themselves in the West in order to commit all sorts of predatory crimes, such as burglary, shoplifting, armed robbery, and the skimming of debit and credit cards (Spapens, 2008).

In turn, Eastern European and former Soviet countries themselves became the sources of victims of human trafficking, who worked in Western Europe either in appalling conditions or as prostitutes. Traders in former communist countries sold their surplus of small arms and light weapons to traffickers, who delivered them to combatants in the conflict zones of Africa, for example (cf United Nations, 2001). Finally, the regime changes in, for example, Russia and Albania led to the emergence of indigenous organized crime groups who also became involved in the trafficking of illicit drugs, for example.

In Europe, the abolishment of fixed border controls in the Schengen zone made it easier for itinerant groups to move around, but it also simplified the trafficking of stolen goods

and illicit drugs across borders, particularly after the expansion of the zone in 1999. Furthermore, increasing economic and social integration in the European Union (EU) border areas after Schengen promoted a rise in cross-border petty crime, especially in densely populated border areas (Spapens, 2010a).

Generally speaking, mobility and migration increased substantially in the past two decades. In the 1990s, criminals smuggled growing numbers of Chinese migrants to Europe and North America, for example (Zhang and Chin, 2001). These trends also enabled itinerant gangs to operate across longer distances. The notorious 'Pink Panther gang,' a network originating in Serbia, which is suspected of having conducted over 100 robberies of jewelry stores in over 20 countries, is a noteworthy example. Finally, it is now far easier than in the past for migrants from different parts of the world to visit relatives in their home countries, and those who are willing and able to engage in illegal activity have less difficulty finding and exploiting illegal market opportunities.

The revolution in information and communication technology and, in particular, the rise of the Internet-created opportunities to commit new types of cross-border crime and modernized traditional forms. An example of this, documented a few years ago, is a Chinese crime group that had bought credit card information hacked by a group of Ukrainians and used it to falsify credit cards to buy designer goods in Paris and Brussels (Spapens and Fijnaut, 2005). Another example is the emergence of online gambling in the mid-1990s. It is usually illegal to operate a gambling website without a license issued by the State in which one is offering the service. The Internet, however, knows no borders and has thus disrupted the regulatory regimes based on sovereignty. It is especially problematic that most of the ultimate beneficial owners of gambling websites are unknown. Online gambling also globalized traditional types of crime, such as match fixing (Spapens, 2012b).

Finally, environmental crimes also emerged as a global concern. Of course, pollution problems plagued humans, flora and fauna in the past as well, but it was not until the 1960s that it became a crime to inflict damage on the environment. Environmental crimes may be transnational in their effect, such as the polluting of air and water. They may also concern trafficking, for example in hazardous waste from an industrialized nation to a Third World country. Mobile environmental crime may, for example, involve the captain of a ship constantly dumping waste, such as bilge water, instead of offering it to a specialized harbor facility for processing. Finally, cross-border environmental crime may even take place in cyberspace, for example, by committing fraud in emission trading schemes (Spapens, 2010c).

Transnational Crime Networks

Traditional diasporas such as the Chinese and Jewish have always played an important role in international trade. Bonds of trust between communities spread out across the globe offered a secure basis for business agreements (cf Weidenbaum and Hughes, 1996). Understandably, traders in illicit goods also made use of such networks and trust relationships. The 'Kosher connection,' for instance, played an important role in the trafficking in ecstasy from the Netherlands to the United States in the 1990s (Spapens, 2006). Of course, transnational banditry depends in the first instance on mobility, but itinerant gangs also misuse immigrant communities, for instance to obtain temporary lodgings. One example is Albanian criminals in the Belgian city of Liège, who forced members of the immigrant community to assist them by threatening to harm family members still living in Albania (Farcy, 2002). Nowadays, migrant communities from all over the world reside in the cities of the industrialized West, and (illicit) trade can easily follow from connections with associates or family members still living abroad. Whether crime groups can actually exploit such links will depend on whether there is a market, for example, for specific illicit products and services, stolen goods, and dumping waste.

Particularly since the fall of the Iron Curtain, authorities worry about the risk of organized crime networks turning into global crime multinationals (cf Strange, 1996; United Nations, 2004; Williams, 2003). Such networks may spread their activities across the world, operating from safe havens where governments and law enforcement institutions are weak (cf Godson, 2003).

Theoretically, foreign crime groups can undermine other societies in three basic ways. First, such groups may move to another country to provide additional illegal goods and services or take over the markets of existing providers. Second, crime networks may set up shop abroad to commit predatory crimes, including extortion. Third, they may invest their criminal gains in legitimate economic activities in other countries (van Dijk and Spapens, 2013).

Although it is not difficult to present examples, foreign crime groups almost never operate parallel to existing local crime networks. Instead, they are always connected through personal or business relationships. The only notable exception is truly mobile groups such as the Pink Panther gang mentioned above. Seeking cooperation is far more rewarding than trying to outcompete established local crime groups and thus sparking violent responses. Furthermore, in countries with homogeneous populations, foreign criminals stand out, and their illegal activities may more readily attract the attention of law enforcement. Finally, it is difficult to introduce new types of organized crime, such as extortion and racketeering, in countries with functioning legal systems. Ironically, it is also complicated in places where government is weak, because chances are that powerful crime groups already exist in such circumstances (van Dijk and Spapens, 2013).

The question remains whether 'masterminds' control the activities of foreign criminals who have connections with crime syndicates such as the Italian Mafia, the Chinese Triads, or the Russian Mafiya. The police often assume that this is the case, particularly if they observe a suspect who is residing in their country regularly flying back to China, Russia, or Italy. Although foreign criminals may use such connections to gain support, for instance financial assistance, there is no proof that others run the illegal operations from abroad (van Dijk and Spapens, 2013).

It is clearly easier now to establish and maintain cross-border criminal relations, to commit predatory crimes over longer distances, and to carry out certain illegal activities on the Internet than just a few decades ago. However, criminals must still operate without any legal protection in violent

surroundings and with the constant risk of colleagues robbing them, and they are therefore especially vulnerable when trying to expand their business to other countries or even within their own country (Varese, 2011).

The Legal Framework

Operating across borders presents specific difficulties for organized crime groups but it also poses a challenge to law enforcement. When talking to police practitioners, one can often hear the complaint that international law enforcement cooperation is in many respects 'not working.' Cooperation is often slow and requires all sorts of formalities. The core principle of the criminal justice system is the sovereignty of the State. As a rule, it will not accept foreign police officers operating in its territory or other countries prosecuting suspects for acts committed within its borders, with the exception of certain limited and well-defined cases. Cross-border operational law enforcement cooperation thus depends on a system of requests for mutual legal assistance.

This section briefly addresses the legal framework for cooperation in criminal investigations. It leaves aside extradition and other important instruments, such as capacity building and conventions in which States agree to take specific action against certain forms of crime. An example of the latter is the Convention on International Trade in Endangered Species of Wild Fauna (CITES), which prohibits the trade in certain species of animals and flora. However, CITES does not provide for the exchange of requests for mutual legal assistance following an actual criminal investigation.

There are conventions on mutual legal assistance at different levels. The most comprehensive in terms of participating States are the United Nations Convention against traffic in illicit drugs and psychotropic substances of 1988 and the United Nations Convention against transnational organized crime and the protocols thereto of 2004.

The first enables the parties to afford one another the widest measure of mutual legal assistance in investigations, prosecutions, and judicial proceedings in relation to criminal offenses involving illicit drugs and psychotropic substances listed by the UN. The forms of assistance available include taking evidence or statements from persons, facilitating the service of judicial documents, executing searches and seizures, examining objects and sites, and providing information and evidence. It also allows for the transfer of proceedings and controlled deliveries of shipments of illicit drugs. The United Nations adopted the Convention against transnational organized crime on 15 November 2000. This convention covers only transnational serious crime, which it defines as "conduct constituting an offence punishable by a maximum deprivation of liberty of at least 4 years or a more serious penalty."

Another convention to which a substantial number of countries are party is the Commonwealth Scheme for Mutual Assistance in Criminal Matters of 1990 (Harare Scheme). The Commonwealth of Nations now includes 53 Member States, with 1.9 billion inhabitants. It provides for assistance similar to the UN Conventions described above but also includes provisions for facilitating the personal appearance of witnesses; temporarily transferring persons in custody to appear as a witness; tracing, seizing, and confiscating the proceeds or instrumentalities of crime; and preserving computer data such as traffic data.

In Europe, the European Convention on Mutual Assistance in Criminal Matters of 1959 was the first important multilateral treaty concerning police and judicial cooperation in Europe. Drawn up by the Council of Europe, it provides for the exchange of formal requests for mutual legal assistance (letters rogatory). Such requests describe the offense or offenses under investigation and, if known, the identities of the suspects involved as well as the assistance required. The requested party can only comply if the offense is also punishable under its own domestic penal law. The Convention includes specific provisions for interrogating suspects, interviewing witnesses, searching premises, and exchanging information from criminal and judicial records. A party may also request another to institute proceedings in its own territory. The 1959 Convention has entered into force in all of the 47 member states of the Council of Europe, and in three nonmember states (Chile, Israel, and Korea). It also served as a template for the UN Conventions and the Harare Scheme mentioned above, as well as for many bilateral treaties.

The Maastricht Treaty established the European Union in 1992 and gave the EU competence in the field of justice and home affairs. It led to many new provisions for operational law enforcement cooperation. In 1998, the Treaty of Amsterdam incorporated the Schengen Implementation Convention into the legal framework of the EU. 'Schengen,' originally the initiative of Belgium, France, Germany, Luxemburg, and the Netherlands, introduced the free movement of persons, goods, capital, and services between these countries. However, 'open borders' also called for measures to enhance police cooperation, to prevent criminals from taking advantage. Thus, the Schengen Implementation Convention provides for the direct exchange of information between the police forces and for cross-border pursuit, cross-border surveillance, and controlled delivery of illicit drugs.

In May 2000, EU Member States signed the Convention on Mutual Assistance in Criminal Matters between the Member States of the European Union. It includes an extensive framework for intercepting telephone conversations and contains provisions with regard to cross-border covert operations. Moreover, it formally introduced joint investigation teams as a means of enhancing operational police cooperation. The convention also extended existing provisions, for instance by enabling telephone or videoconference interviewing of witnesses and experts.

More recent instruments are the 'Framework Decision on simplifying the exchange of information and intelligence between law enforcement authorities of the Member States' (2006) and the 'Framework Decision on the stepping up of cross-border cooperation, particularly in combating terrorism and cross-border crime' (2008). The first expands and simplifies information exchange between the EU member states. The second introduces, among other things, online access to databases of DNA profiles and fingerprints on a hit/no-hit basis. In other words, the police can check online if a match is available abroad. If this is the case, the competent authority can send a request for mutual legal assistance to ask

for further details. It also contains articles specifically concerning cross-border public-order policing.

Apart from engaging in multilateral conventions, countries can also agree to bilateral arrangements on mutual legal assistance. The United States, for example, has concluded such treaties with over 40 countries. Finally, if no treaties or applicable provisions exist, the national authorities of the countries involved can decide on providing mutual assistance in individual cases subject to specific agreed terms and conditions.

The Organizational Framework

Effective international law enforcement cooperation requires an organizational infrastructure for handling requests for mutual legal assistance (Spapens, 2010b). This section briefly discusses the most important multilateral arrangements at the international and EU levels. It includes Interpol, Europol, police-liaison networks, and, finally, the European Judicial Network and Eurojust.

Interpol, now with 188 Member States worldwide, is the best-known global institution for police cooperation. One of its main tasks is to maintain a network of National Central Bureaus that can exchange information on a 24/7 basis. In addition, Interpol provides data services, maintains databases of police information, and offers operational support to national and international investigations through its specialized crime units and 24/7 command and coordination center. Interpol also provides training and support to the police with regard to fighting cross-border crime. However, contrary to what the public may think, Interpol itself has no operational investigative powers. Its role in the Second World War resulted in its powers being severely restricted with respect to ideological crimes. Article 3 of the Interpol Constitution specifically forbids the organization 'to undertake any intervention or activities of a political, military, religious or racial character.' However, after the attacks on the World Trade Center in 2001, Interpol did become involved in the fight against terrorism.

Networks of police-liaison officers also have an important role to play in law enforcement cooperation. Their primary task is to assist in information sharing for the purpose of combating crime through both prevention and law enforcement and by responding to requests for mutual police and judicial assistance in criminal matters. Liaison officers have no executive powers and they cannot investigate crimes independently on foreign territory. The exchange of police-liaison officers is usually the result of a bilateral agreement and often mirrors lines of cross-border crime. The Netherlands, for instance, already had a liaison officer in Thailand in the 1970s because, at that time, Southeast Asia was a major source of heroin. Large-scale trafficking in ecstasy from the Netherlands to Australia after the turn of the millennium led to the posting of a Dutch police liaison in Australia and vice-versa.

Finally, the European Union established three institutions to support law enforcement cooperation in the fields of serious crime and terrorism in particular. First, Europol was founded in 1999, although the idea for creating a European criminal investigation department had already been raised in the 1970s (Oberleitner, 1998). Although originally envisioned as a Federal Bureau of Investigation for the EU, Europol still does not have executive powers and remains a 'clearing house for information.' Europol's office is in The Hague in the Netherlands. Europol can also handle information requests with regard to terrorism.

In the field of judicial cooperation, the European Judicial Network (EJN) began its work in 1998. This network consists of the national judicial authorities of the EU member states, each of which has assigned one experienced public prosecutor to the EJN. The primary aim of the network is to support the exchange of requests for mutual legal assistance. For instance, the EJN can assist public prosecutors who want to contact an authority in another Member State and assist in formulating requests for mutual legal assistance.

The final important international institution is Eurojust, also with its offices in The Hague. This organization was founded in 2002 in order to facilitate law enforcement cooperation between the EU member states, especially in the field of organized crime. If necessary, Eurojust can host meetings between criminal investigators from two or more Member States working on cross-border cases and furnish facilities for simultaneous interpretation.

Conclusion

This article has shown that criminals have always tried to take advantage of borders between jurisdictions and States, to avoid apprehension and punishment, to find targets for predatory crimes, and to exploit market opportunities for illicit goods and services arising from differences in supply and demand as well as differences in laws and regulations. From the 1960s onward, the growing demand for illicit drugs promoted the development of a 'glocal' network of producers, traffickers, and dealers. Particularly since the late 1980s, the increasing level of mobility, the fall of the Iron Curtain, and the popularization of the Internet have presented new opportunities for cross-border crime. Specific features of the 'underworld,' however, seem to prevent the emergence of multinational criminal organizations. Notwithstanding these problems, criminal networks appear to be more effective in operating across borders than their counterparts in law enforcement. Despite the development of an impressive legal and organizational framework to aid cross-border investigation, sovereignty remains the basic principle. Cooperation through requests for mutual legal assistance is notoriously slow and inefficient. Mechanisms that could be more effective, such as joint investigation, are still in their infancy, however, even in the EU.

Transnational Religious Identities (Islam, Catholicism, and Judaism): Cultural Concerns

Dale F Eickelman, Dartmouth College, Hanover, NH, USA

Abstract

'Transnational religious identity' refers to personal or collective religious identities that transcend enclaves, localities, regions, nations, and states to achieve a wider unity of belief, practice, and community. The term implies the existence of the nation-state as the principal worldwide form of political sovereignty. Transnational religious identities are continuously reconstructed in differing contexts and ongoing struggles over ideology and authority in which shifting coalitions of elites, counterelites, ethnic groups, and those excluded from local authority structures compete for voice and recognition.

The subject of 'transnational religious identity' is unexpectedly complex. It refers to personal or collective religious identities that transcend enclaves, localities, regions, nations, and states to attain a wider unity of belief, practice, or community. Transnational religious identities also imply an inherent tension between claims to universality and the specifics of language, ethnicity, place of origin, locally shared culture, values, and history. The term also implies the existence of the nation-state system – with its own competing claims for personal and collective identity – as the principal worldwide form of political sovereignty. Transnational religious identities are continuously reconstructed in different contexts and ongoing struggles over ideology and authority in which shifting coalitions of elites, counterelites, ethnic groups, or those excluded from local authority structures compete for voice and recognition.

Constructing Religious Identities

Transnational religious identities, like other personal and collective identities, are socially constructed. They are not given or 'natural,' although the advocates of some religious identities, like secular nationalists, often make such claims. In the nineteenth century, William Robertson Smith's influential *Lectures on the Religion of the Semites* (Smith, 1956) traced the development of Semitic religious practices and institutions, stressing how a people's social and political institutions, and the shifting boundaries between their own and 'other' communities, contributed to shaping their religious and ethical conceptions. Thus, the prophecies of Ezekiel and Samuel differed not because of a contradiction in the Bible, but because each prophet addressed himself to different groups and historical contexts.

For Smith and his successors, a key element in the growth and development of religions was the growing awareness that ideas and practices of community are socially constructed even if they are firmly rooted in divine revelation. In this view, a more 'modern' understanding of religious belief and practice implies a self-consciousness of ritual and tradition, places a high value on individual responsibility and commitment, and recognizes the existence of other religions and accords them some measure of legitimacy. In Christianity, Islam, and Judaism, this individual 'taking charge' of faith and practice also led to the greater role of a nonclerical 'public' in determining the role of religion in society (Salvatore, 2007). In this respect, Quranic verses such as the following, revealed in seventh century Arabia, are distinctly modern: "To each among you, we have ordained a law and assigned a path for each of you. Had God pleased, he could have made you one nation, but His will is to test you by what He has given you; so compete in goodness" (Quran 5: 48). From its beginnings in seventh-century Arabia, Islam as religious tradition and practice has been remarkably open to the outside world (Ernst, 2011). The vast expanse of the Muslim majority world, ranging from Morocco to Indonesia, inevitably meant that it came to encompass a variety of civilizations and cultural forms. In Arabic, the Quran exhorted its initial seventh-century audience to break through parochial identities of tribe and kinship and aspire to a wider, more inclusive community of belief and practice.

Other religious traditions, including Judaism and Christianity, show similar diversity of form and interpretation, commingling local and universal elements. Pilgrimages in all faiths serve to project believers across lines of immediate locality or group. Pilgrims – and visitors to shrines and holy places – set off from home in the hope of reaffirming contact with a spiritual center, encountering 'others' and returning home with a sharpened awareness of difference and similarity (Eickelman and Piscatori, 2003; Sumption, 1975). Whether to Mecca, Jerusalem, Ayodhya, Rome, the holy places of Shi'a Muslims, or to the shrines of Sephardic saints (*zaddiqim*) in North Africa and Israel, pilgrimages and visitations create unity as they highlight differences of locality. In the Mediterranean (for Christians, Muslims, and Jews), as for South Asia (for Hindus and Muslims), pilgrimages and visitations often involve shared sacred spaces (Albera and Couroucli, 2012; Pemberton and Nijhawan, 2008).

Catholic missionaries and the adepts of Sufi religious brotherhoods also carried the word and practice of their respective faiths across vast spaces before they became nation-states (Rudolph and Piscatori, 1997). The missionary activities of the Catholic Church in Latin America date from the Spanish conquests of the sixteenth century. Missionary orders such as the Jesuits and Franciscans implanted complex networks of churches, missions, and schools, transferring people and

resources between Spain and the colonies. In the Middle East in the nineteenth century, French Catholic and American Protestant missionaries opened religious schools in the Levant, and from the 1880s onward, the Alliance Israélite Universelle sent emissaries throughout North Africa and the Ottoman Empire. Although not primarily religious in orientation, Alliance missionaries had a profound impact on the self-perception of the Jewish communities where they worked. The work of these missionary enterprises was aimed, respectively, at Christians and Jews. These activities occurred within a framework of economic hegemony and political domination in which foreign powers actively sought to protect the interests of Middle Eastern Jews and Christians. However, these 'minority' communities were widely distributed geographically throughout the Middle East in the nineteenth century, so that missionary activities aimed at them had a significant indirect impact on the region's Muslim majority. For example, the founder of the Muslim Brotherhood, Hasan al-Banna (1906–49), a strong opponent of Christian missionaries in Egypt and elsewhere, may have been strongly influenced by what he saw of their activities and organization when he was posted as a primary school teacher to Isma'iliya, a town in the Suez Canal Zone, in 1927. Such 'learning' from other religious traditions is an important element in transnational religious movements and not confined to the last two centuries (Höfert and Salvatore, 2004).

Sufi orders had a major role in propagating Islam, both in the Islamization of North Africa and in the subsequent consolidation of Islamic domination. Some orders, such as the Bektashiya, attracted as adepts the political elite of the Ottoman Empire. Others, such as the Tijaniyya, had a major role in the spread of Islam to West Africa. Some orders were highly structured, but most were only loosely linked through informal but pervasive networks of affinity and trust. Their forms of association were widely understood and respected throughout the Muslim world, and their organizational forms continue to serve as a template for many contemporary religious movements.

Religious Identity and Nationalism in the Nineteenth Century

In nineteenth century Europe, the idea took hold that peoples could be divided into nations sharing a common language, religion, ethnicity, and culture, and therefore should form separate political units. This notion was complemented by a heightened self-consciousness, systematization, and explicitness of religious traditions. By the 1830s, the plural 'religions' came into common currency, with a similar development in Arabic, to signify the idea of 'religion' as a system of beliefs and practices that could be set alongside nonreligious elements of the human condition and apart from other religions (Smith, 1963). This idea added impetus to the erosion of clerical authority over public discussions about religion in all faiths, an idea that often crossed from one faith to another (Höfert and Salvatore, 2004), as in the heated discussions between Ernest Renan and Jamal al-Din al-Afghani.

The linkage between nationalism and religion was implicit and the boundaries of religious and national identities rarely coincided. Partially in response to political and ideological developments in nineteenth-century Europe, a pan-Islamic movement developed in the late nineteenth century. Although the pan-Islamic movements of the 1880s bore similarities to the pan-Hellenic and pan-German movements of the time, only pan-Islam was based formally on a religious commonality (Landau, 1994). The pan-Islamic movements were initially confined to the educated elite, although this elite claimed to speak for all Muslims. The combined French and Spanish effort to crush the rebellion of Abd al-Karim al-Khattabi in 1927 generated protests throughout the Muslim world and appeals for pan-Islamic unity, but the results were transient and minimal. Equally profound is the accelerated nonelite transformation of world religions as they incrementally are influenced by the diverse national contexts in which they develop. For example, some observers write of the birth of a 'French Islam' (Kepel, 2011, p. 11).

The Reemergence of Religion in Public Life

Prevailing theories of modernity and modernization in the mid-twentieth century assumed that religious movements, identities, and practice had become increasingly marginal to modern or modernizing societies and that only those religious intellectuals and leaders who attached themselves to the nation-state would continue to play a significant role in public life. As Casanova (1994) notes, by the late 1970s this prevalent view rapidly eroded through the impact of several nearly simultaneous developments: the Iranian revolution, the rise of the Solidarity movement in Poland, the role of liberation theology in political movements throughout Latin America, and the return of Protestant fundamentalism as a force in American politics. Religion continues to play a significant role in politics and society worldwide. Even locally rooted movements benefit significantly with transnational sponsors or supporters, whether emigrants, states, or others sharing a group's objectives. Opposition to the Shah's regime was firmly rooted in Iran, but the safe haven provided for opposition leaders in exile and their transnational ties and freedom of movement and action were integral to the revolution's success, just as such transnational ties contribute strongly to reshaping how Iranians think of Islam and politics in the era of the post-1979 Islamic Republic (Adelkhah, 2012).

Contemporary religious transnationalism and the identities it supports take many forms. Some are highly structured, while others are only informally organized and related primarily by affinity of goals. Informality and the lack of formal structure can be a strength in contexts of political and religious oppression.

At one end of the spectrum of organizational structure is the vertical transnationalism of the Roman Catholic Church. In its encounter with the emerging system of sovereign nation-states in Europe, the Church incrementally reached an accommodation with nation-states so that the Church hierarchy, although transcending the boundaries of nation-states, also worked within them. The close ties formed with sovereign states often preserved a large measure of local freedom of action for the Church, but they also checked its ability to serve as a voice for social and political reform and for human rights.

The Second Vatican Council (1962–65) significantly altered the nature of Catholic transnationalism. With the Vatican's Declaration of Religious Freedom, *Dignitatis Humanae*, it unambiguously supported the doctrine of universal human rights and used its voice internationally to secure these rights for all peoples and not just Catholics. Vatican II also intensified interfaith dialogue and formally recognized the diversity of Catholic belief and practice. It spurred the translation of liturgies into local languages and promoted lay participation in Church activities, further adapting the Church to local political and social circumstances.

The Church's overall hierarchical structure remained intact after Vatican II, but it was complemented and sometimes overshadowed in importance by decentralized grassroots networks and organizations created for purposes as diverse as Bible study, evangelism, and social and political actions. Many organizations and networks had direct ties to the Church hierarchy, while others operated autonomously. In Latin America, as elsewhere, both types of networks benefited from transnational support. Dutch, Italian, French, Swiss, the United States, Spanish, and other organizations acting transnationally contribute funds and personnel to sustain local developmental programs and action networks. Church-related human rights networks (along with groups with no religious affiliation, such as Amnesty International and Human Rights Watch) have played a significant role in sustaining resistance to authoritarianism and repression, giving concrete form to the idea and practice of transnational civil society.

Protestant transnationalism lacks the time depth of the Catholic presence in Latin America, Africa, and elsewhere, but missionaries from mainline Protestant denominations established a stronghold in Africa by the last part of the nineteenth century, often informally dividing spheres of influence with competing Catholic and Protestant groups, establishing schools and hospitals that often had no state counterparts. Schools have been especially important, and often formed the cadres of early nationalist movements (Beidelman, 1982). Education, intended to inculcate Christian identity and practice, ironically undermined colonial authority and provided the cadres for African independence movements.

The first Protestant churches in Latin America were established primarily for European immigrants. By the 1960s, however, the mainline denominations were increasingly displaced by evangelical, Pentecostal, and fundamentalist churches and missionaries, trained and supported primarily from North America. Levine and Stoll (1997, p. 71) describe the growth of these groups, especially the 'Religious Right,' mixing evangelism with nationalism and anticommunism, as 'spectacular.' They suggest that these groups, in addition to providing needed community services, hospitals, and schools in areas where state facilities are minimal, appeal primarily to people experiencing intense social change and aspiring to improve their status and lives.

The ease of travel and the greatly enhanced role of the mass media have also enhanced the scope and ability of nongovernmental associations and networks to infuse an inherent transnational dimension to contemporary religious identity and practice. Once established, the 'horizontal' networks of civic and religious engagement for both Catholic and Protestant groups became durable and self-sustaining. The transnational ties engendered through travel for labor migration, missionary activity, civic action, and human rights work creates both institutional ties and a sense of moral community for all participants, not just for the elite. Unlike the hierarchical transnationalism of the Church in earlier periods, the loose network organization that characterizes many contemporary groups is more difficult for states to regulate or control. Moreover, the ease with which participants in such networks can spread information across state boundaries and secure external support serves as a brake on the state abuse of authority. This is as much the case for Latin America as elsewhere. Della Cava (1993), for example, notes the influential role of Catholic nongovernmental philanthropic and service organizations in Central and Eastern Europe as a catalyst for change and an alternative, although not a replacement, for attachment to the nation-state.

Transnational Islamic Identities

Islamic transnational movements occur in a significantly different context than Christian ones because Islam lacks a central organizational hierarchy. Although some Muslim intellectuals call for a spiritual or political unity, the Muslim world has almost always been characterized by a *de facto* pluralism of belief and practice. Even radical Islamic groups such as Lebanon's Hizbullah use the universal language of Islam but in practice seek only to establish an Islamic state or an Islamic order within their respective national borders even if they secure external support (Norton, 2009).

Some Islamic transnationalism is formal, organized, and linked to state organizations. After an arsonist's attack on the al-Aqsa mosque in Jerusalem in 1969, Muslim majority states founded the Organization of the Islamic Conference (OIC), which consists of 56 member states. However, this group has never advocated political unity and some member states, such as Nigeria, are anxious not to appear too closely identified with the organization. Nor has the OIC proved effective in the Iran–Iraq war (1980–88), in defusing the Iraqi–Kuwaiti tension that led to the 1990–91 Gulf War, or in other conflicts among Muslim majority states. However, its Islamic Development Bank, established in Saudi Arabia in 1974, has become one of the most effective aid agencies in the developing world, and various charitable funds associated with it have had a significant impact in its regions of activity.

Unlike Catholicism, in which vertical and horizontal transnationalism coexist, Islamic transnationalism is entirely horizontal. In addition to formal organizations such as the OIC, some clandestine or 'deniable' transnationalism is state supported. After the Soviet invasion of Afghanistan in 1979, for example, the United States, with the cooperation of Pakistani and Saudi Arabian security services, supported the recruitment and training of mercenaries from other countries, including Egypt, Algeria, the Yemen, and Sudan to operate alongside Afghan refugees from bases in Pakistan. This 'joint venture' subsequently turned against its initial sponsors. Relationships among like-minded groups are highly fluid, with loosely organized networks of ideological support, financing, and practical training (Sageman, 2008).

Islamic transnationalism is also manifested in nongovernmental movements such as the Muslim World League (*Rabitat al-'alam al Islami*). It sponsors educational programs, religious scholarships for students to study at Saudi and Muslim world universities, and a vigorous publication program throughout the world. Such nonstate organizations, particularly through their formal presentation of Islamic issues and standardization of language and approach, help create common ideological communities that transcend state and national frontiers. Such organizations also show an increasing concern over the situation of Muslim minorities throughout the world, bringing their plight to the wider Islamic community worldwide. The concern of these groups with Muslims living in North America, Europe, and Australia is reciprocated by the emigrants' active concern with the situation of coreligionists in their countries of origin or heritage and with the situation of Muslims in general. Other movements, such as those associated with the Turkish religious leader, Fetullah Gülen, are based on loosely connected clusters of supporters who lack formal central direction. Gülen's movement sponsors schools throughout Turkey, Central Asia, and Eastern Europe, as well as radio, newspaper, and television stations; notwithstanding the lack of central organization, the movement's educational and media programs have emerged as one of the most enduring forms of Turkish presence in Central Asia and Turkish immigrant communities in Europe, North America, and Australia (Turam, 2006).

An even less formal and structured form of transnationalism is represented by *da'wa* (call to Islam) movements such as the Tablighi Jama'at (Masud, 2000). Founded in India in 1927, the movement expanded worldwide after 1947 and currently operates in 80 countries. One principle of the movement is that the practice of Islam does not depend on educated elites alone. The movement's main efforts are directed at deepening the faith of other Muslims and, to promote unity, it avoids theological controversies and politics. South Asian in origin, the Tablighi Jama'at is also active in Europe, North America, and the Arab world. The movement offers no formal training institutes, although some institutions of religious learning are attached to Tablighi centers. Unlike other Muslim organizations, the Tablighi Jama'at lacks welfare or educational programs. Since the movement eschews the broadcast and print media as a matter of doctrine, its spread is entirely through personal contact. With its emphasis on strict adherence to rituals and a concern with the development of individual morality and renewal of personal faith rather than collective action and community change, the Tablighi movement has limited appeal to educated Muslims.

Religious Identity and Globalization

Since the last third of the twentieth century, modern forms of travel, communication, and mass education have accelerated religious transnationalism – the flow of ideologies, access to information on organizational forms and tactics, and the transformation of formerly elite movements to mass ones – rendering obsolete earlier notions of frontier as defined primarily by geographical boundaries and accelerating in pace the earlier spread of ideas already speeded through the introduction of print technologies. Thus, the devotees of the North African Jewish saint, Baba Sali (Rabbi Israel Abouhatzeira) meet not only in Israel and Morocco, but also in New York and Europe.

Especially in the Muslim majority world, the advent of mass higher education since the mid-twentieth century, combined with the proliferation of mass media and the greater ease of communication and travel, has led to a significant reimagining of religious and political identities. One change is that patterns of authority have become more diffuse and open. Religiously committed activists increasingly replace traditionally educated scholars as sources of authority. Second, religion has implicitly been systematized and objectified in the popular imagination, making it self-contained and facilitating innovation. Questions such as 'What is my religion?', 'Why is it important to my life?', and 'How do my beliefs guide my conduct?' have become foregrounded in the lives of large numbers of believers, facilitating individual questioning and encouraging individuals to assume responsibility for their conduct and to participate in movements of social and political action. These transformations also mean that 'authentic' religious tradition and identity are foregrounded, questioned, and constructed rather than taken for granted. Finally, the greater access to education, like access to the mass media, has broadened senses of language and community. Just as the rise of written vernacular languages in Europe since the sixteenth century and the spread of print technology created language communities wider than those of face-to-face interactions, mass education and mass communications play a role in the contemporary world, transcending the narrow bases of local communities and dialects and creating new, if fluctuating, bases of religious identity.

Abstract

Transportation geography describes, explains, and predicts flows of people, goods, and information across space. Flows occur as a result of some form of exchange: people offer their services to employers in exchange for wages, friends exchange information about spouses and children, manufacturers produce and sell consumer goods to wholesalers and retailers. Flows occur within a network: the journey to work in vehicles on roads or rail, information via telephone lines or the Internet, and goods across roads, rail, shipping lanes, or air route. Other subfields of geography are concerned with places and their spatial organization. Places and flows are interdependent; hence the boundaries of transportation geography are quite fluid. This article describes the fundamental concepts of transportation geography, discusses major theories, and highlights the current state of research.

Understanding Flows

Transportation is critical to contemporary society. In the United States (US), the transportation sector represents around 9% of the gross domestic product (GDP), and transportation is the second largest expenditure category for households. Interestingly, its share of GDP is declining as transport industries become more efficient. Economic growth is closely linked with transportation: movement of people and goods is positively associated with GDP. Why is transportation so critical, and what motivates these flows? Transport is costly, both in terms of time and money. Hence there must be some benefit to justify incurring these costs. Flows occur when the benefits derived from transport exceed transport costs. Flows can be understood in terms of a few basic principles.

Flow Depends on Transport Costs and Gains from Trade

The first principle of flows can be illustrated with the journey to work. Consider a worker: the cost of commuting is incurred in order to remain employed. How much is a worker willing to pay in order to receive a given wage rate? The average US commute is estimated at around 28 min (Santos et al., 2011); and just 7.5% are longer than 1 h (McKenzie and Rapino, 2011). Since commute costs reduce the effective wage (wages net of commute costs), it follows that as commute costs increase, fewer people will be willing to accept employment at a given wage level. The converse also holds: as commute costs decrease, more workers will be willing to accept employment at a given wage level. The likelihood of flow taking place is a function of transport costs and benefits from trade. This principle applies to goods and information as well as people.

Declining Transport Costs Are Associated with Increased Flows

Transport cost includes both time and money costs. Technological change and infrastructure investment have increased travel speeds and reduced unit costs. The late nineteenth century transcontinental railroad offered trips from New York to San Francisco in 6 days; the trip by air today takes about 6 h. Similarly, France's high-speed train offers service from Paris to Lyon in 2 h. Around 1900 the same trip would have taken 6 or 7 days. These improvements also apply to intrametropolitan travel, but to a lesser extent, since intrametropolitan travel has so far been limited to surface transport modes and involves shorter distances. Transport cost has also greatly declined. For example, it is estimated that the average cost of commuting by streetcar in the US at the turn of the twentieth century was about 20% of the average daily wage (Giuliano, 1989). Today the average cost for automobiles commuters is about 4% (Roberto, 2008).

Increases in speed result in 'time/space convergence,' a reduction in friction of both distance and time. Time/space convergence is illustrated in Figures 1(a) and 1(b) for all of Europe, excluding Russia and the Ukraine (Spiekermann and Wegener, 1994). **Figure 1(a)** provides actual spatial relationships and is calibrated on a homogeneous travel speed of 60 km/h **Figure 1(b)** provides a picture of temporal relationships, based on the 1993 rail transport network. Note that Paris is 'closer' to major cities of Switzerland, The Netherlands, and Amsterdam, while in East Europe, Bucharest and Sofia are both 'farther' from one another and from Central Europe. The 1993 rail network does not account for the high-speed rail links that have been built in Europe during the past two decades. These links have further changed time/space relationships.

Time/space convergence is associated with globalization and the emergence of the time-sensitive economy. Dicken (2011) argues that improvements in shipping (containerization, air transport, and information and communication technology (ICT)), together with trade and investment liberalization policies, explain the rapid globalization observed over the past several decades.

Reductions in transport costs, in absolute terms and relative to per capita income, along with increased demand due to population growth have resulted in large increases in passenger and freight travel. **Figure 2** shows the increase in the US passenger-miles (private vehicle and domestic air service) between 1960 and 2005, and US domestic surface freight transport ton-miles between 1980 and 2004. **Figure 3** shows the increase in total inland passenger-miles (all modes) and total inland freight ton-miles (all modes) for five select major industrialized nations (OECD members) over the 1980–2005 period.

Figure 1 Time/space convergence. (a) Panel A: Map of Europe, constant travel speed. (b) Panel B: Map of Europe, 1993 rail transport network.

Figure 2 US transportation trends. (a) Panel A: Passenger-miles of travel for privately occupied vehicle (POV) and air carrier. (Data from US DOT Bureau of Transportation Statistics (http://www.rita.dot.gov/bts/) Note: 1 mile = 1.61 km.) (b) Panel B: Domestic freight ton-miles. (Data from US DOT Bureau of Transportation Statistics (http://www.rita.dot.gov/bts/) Note: 1 mile = 1.61 km and 1 Ton = 1000 kg.)

Declining Transport Costs and Increased Flows Are Associated with Development of the Space Economy

Historical development of the space economy is explained in part by declining transport costs. In the preindustrial era, nonmotorized transport was slow and difficult. There was little exchange between cities, because transport costs exceeded benefits at very short distances. Technological changes that reduce transport cost, e.g., 'space-adjusting technologies,' allow regions to exploit comparative advantage, engage in regional specialization, and expand their areas of economic influence (hinterlands).

Nonmotorized modes of the preindustrial era were replaced with motorized modes in the nineteenth century: steamships and railroads. These technological advances greatly reduced the cost of intercity travel and hence led to large increases in both passenger and goods transport. The railroads in the US connected vast regions, resulting in the emergence of an integrated national economy. Railroads also contributed to the development of the national economies in Europe. Change accelerated in the twentieth century with the emergence of paved roads, automobiles and trucks, and the development of commercial air transport.

Figure 3 Transportation trends in select major global economies. (a) Panel A: Total inland passenger-miles of travel (all modes). (Data from OECD (http://stats.oecd.org/) Note: 1 mile = 1.61 km.) (b) Panel B: Inland freight ton-miles (all modes). (Data from OECD (http://stats.oecd.org/) Note: 1 mile = 1.61 km and 1 Ton = 1000 kg.)

A famous example of the impact of reduced transport costs is the Erie Canal, built in 1825 to open a waterway between Lake Erie and New York by connecting Lake Erie to the Hudson River. The reduction in transport cost was dramatic: over-the-road transport costs 20 times as much per ton-mile as shipping via canal; travel time was 20 days over the road and 6 days via canal. Goods movement greatly increased. New York's hinterland was extended through the entire northeast region, and its position as the US center of international trade and the dominant city in the US urban hierarchy was consolidated.

Empirical research on the relationship between transport and economic development is mixed. Research on both developed and less developed countries indicates that transport infrastructure is a necessary but not sufficient condition for economic development (Hoyle et al., 1998). The first links of major networks (rail, highway) have generally had significant impact, while the impact of additional links is more uncertain due to the incremental nature of even large investments when networks are more fully developed. In the case of the US Interstate Highway System, significant impacts of the initial investments are documented, while studies of more recent

investments are mixed (Giuliano and Agarwal, forthcoming). There are also many failed examples of transport infrastructure investments made to promote trade and economic development, as for example, the US efforts to promote economic development in the Appalachian region.

Transport and Urban Spatial Structure Are Interdependent

Urban spatial structure is the outcome of economic, social, political, and cultural forces. Within the complex process of urban evolution, however, transportation has played a major role. The historical relationship between transport and urban form is well established (Muller, 2014). With faster and cheaper transport has come more decentralized and dispersed spatial structure, and as activities have become more spread out, travel has increased. Decreased accessibility has generally been offset by increased travel speeds. But the explosion in travel demand has outpaced capacity expansions; and complexity of travel patterns has made transportation management challenging. The consequence is peak-period congestion on roads and public transport systems. With transport costs therefore increasing in some metropolitan areas, the question is whether a corresponding decrease in travel will take place. One possible indicator is the stability and in some cases decline in private vehicle travel observed in several countries since 2008 (e.g., Boarnet, 2013).

US cities in the latter half of the nineteenth century were crowded and congested. Industrialization had generated a surge of urbanization. The lack of motorized transport forced population and businesses to colocate in close proximity to one another. Electricity-powered rail transport proved to be the breakthrough technology. Starting in the late 1880s, urban railways allowed cities to grow outward as workers took advantage of the new mode to seek less crowded residential locations outside the city core, and gave the city center special dominance as the center of the intracity transport network. Urban rail was followed in the 1920s by the automobile and truck. Development of the highway network proceeded rapidly, increasing travel speeds and allowing ever more rapid decentralization. The post-World War II freeway era continued these trends, with both jobs and population decentralizing, and with the emergence of suburban activity centers. European cities have followed a similar trajectory, but under quite different social, economic, and political conditions, and with – to date – less dramatic spatial change.

The relationship between transportation and urban form has been the subject of much theoretical research. The familiar 'standard model' of urban location and spatial structure as developed by Alonso (1964) and others, serves to illustrate the close relationship between transport costs and urban spatial structure. Consider the simple case of a city where all employment is located at the center, transport cost is a linear function of distance, and households trade-off housing and commuting costs in making their residential location decisions. How will workers locate themselves with respect to the city center? Clearly wages, net of transport costs, will be highest at the city center, where transport costs are near zero; hence workers will prefer location near the center, and locations near the center will be valued higher than locations away from the center. If workers could bid on locations, the result would be a gradient of both land prices and population density that declines with distance from the center. Declining transport cost results in less steep density gradients, as the relative value of living near the city center declines. Decreases in the density gradient have been documented for metropolitan areas in the US and around the world (e.g., Kim, 2007). Declining transport cost (both for goods and passengers) has affected urban spatial structure in complex ways. Employment and population are now concentrated (and growing) in a few metropolitan areas, and simultaneously decentralizing within metropolitan areas (Glaeser and Kohlhase, 2004). Decentralization is characterized by polycentricity and spatial dispersion but impacts on travel are less clear.

Research Issues

Increasing concerns regarding the social and environmental consequences of urban transport, structural changes resulting from development of ICTs, and a changing institutional context in transportation policy decision-making are affecting the research agenda of transport geographers (e.g., Hanson, 2000; Black, 2010). This section discusses three areas of current research: travel behavior; transportation, land use, and environmental costs; and transportation and information technology.

Travel Behavior

Transport geographers have examined personal travel at both aggregate and disaggregate levels of analysis.

Aggregate Models

Various forms of spatial interaction models have been applied in aggregate analysis, most commonly the gravity model. The gravity model incorporates two basic factors that affect the level of flow between places: the population of each place (or some measure of potential for flow), and the distance between them.

The model states that flow from origin i to destination j is a positive function of (1) the potential of the origin zone for generating trips and (2) the relative attractiveness of the destination zone, and is a negative function of the distance between them. Gravity models have been applied to many topics, from intercity transport to local shopping flows.

They have been extended to account for alternative travel destinations (intervening opportunities), differences in nodal characteristics, and differences in travel costs across modes or links. The gravity model has also been widely applied for the estimation and analysis of bilateral trade flows.

Geographic information science has made possible the use of gravity formulations to measure accessibility patterns of different modes or population segments and hence analyze such policy issues as the distributional consequences of urban transport investment. The gravity model plays an integral role in state-of-practice urban transportation planning models: trip distribution (the allocation of trips to specific zonal destinations) is accomplished using a model that accounts for the relative attractiveness of zones as destinations and expresses distance as a generalized cost.

Disaggregate Models

Understanding the travel patterns of individuals is a more complex task. Geographers and economists began to address the issue in the 1970s with the application of utility theory. In this case, travel decisions are discrete choices made on the basis of the utility of each alternative available. The utility of an alternative is a function of its attributes and the attributes of the individual making the choice. Since utility cannot be observed directly, utility-based models estimate the probability that a given alternative will be chosen by observing how people actually behave, or by capturing their stated choice in hypothetical scenarios.

The first applications of discrete choice were made to mode choice problems; later applications included destination choice, route choice, departure time choice, and car ownership. Mode choice models are now routinely used in transportation planning applications. Models have been extended to account for conditional or sequential choices, as for example, mode choice given car ownership. Multilayered models are one approach to developing integrated transportation planning models.

A major theoretical issue in travel behavior analysis is what should be predicted: the trip or the underlying behavior that motivates the trip. Given that travel constitutes a disutility, it is argued that understanding travel requires understanding activity patterns. Termed activity analysis, this approach to travel behavior predicts travel choices as a function of activity choices (Kitamura, 1988).

The roots of the activity analysis approach to travel behavior lie with the Swedish school's time–space geography (Hägerstraand, 1970). In this case the individual has a set of resources (time, money, vehicles) and a set of constraints (schedule, physical and coupling constraints) that define the feasible set of activities they may accomplish over the course of a day. Hagerstrand terms this feasibility area the space–time prism. Activity-based models seek to capture the complex process of choosing a set of daily activities and their location, timing, and sequencing, given feasibility constraints.

Utility-based models assume rational behavior. Travel choices are a function of resources, preferences, and supply characteristics. Some geographers and planners argue that people act as much on attitudes and perceptions as on resources and constraints. Also, travel choices are joint choices (resources and tasks are allocated among household members) which reflect (and affect) underlying attitudes and perceptions. They therefore borrow somewhat from the disciplines of sociology and psychology. Many recent studies have demonstrated the role of personal attitudes and preferences in determining, for example, automobile (Gardner and Abraham, 2010) and public transport (Popuri et al., 2011) mode choice.

Travel as Having Positive Utility

Travel has historically been considered a derived demand. However, some recent research suggests that this may not be the case (Mokhtarian and Salomon, 2001). People may derive pleasure from travel to a far greater extent than assumed. They may conduct activities outside the home in order to travel, or they may travel to more distant destinations because the travel itself is part of the activity experience (take a drive and go out to dinner). Transportation planners have consistently underpredicted the growth in travel demand, even accounting for unanticipated changes in demographics, income levels, fuel prices, and other key factors. Positive utility of travel may explain people's greater-than-predicted propensity to travel.

A related question is whether use of certain modes is associated with greater satisfaction or positive perceptions. Morris and Guerra (2014) found that automobile travelers are happier on average compared to transit riders. Proponents of active transportation (walking, biking, skateboarding, etc.) argue that a shift from motorized to nonmotorized mode of travel can have positive impacts on health and the environment. People who walk and bike have been found to derive relatively greater pleasure out of travel (Morris and Guerra, 2014).

The concept of travel as having positive rather than negative utility has significant policy implications. On the one hand, it helps to explain why travel demand is highly inelastic. On the other, it suggests that efforts to reduce travel for environmental or other reasons will be challenging to accomplish. Planners suspect that those with positive attitudes toward travel (particularly private vehicle travel) may actually be less likely to telecommute or live in dense mixed-use neighborhoods (Ory and Mokhtarian, 2005).

Travel Budgets

Finally, many geographers argue that time budgets determine travel. People make about four (one-way) trips per day and spend an average of about 1.3 h each day traveling. These averages have been observed consistently both over time and across places, ranging from preindustrial agrarian villages to the major developed nations of the world. This consistency has led to the concept of a time budget: people allocate a given amount of time to traveling (Zahavi and Talvitie, 1980). Hence distance traveled is a function of transportation technology and infrastructure. As travel speeds increase (say by construction of a new highway or rail line), people will use travel time savings to travel longer distances. There are two main criticism of the time budget. First, taken to its logical extreme, it conflicts with notions of rationality and utility-maximizing behavior. Second, the empirical observation may be an artifact of central tendency, and therefore may have little value as an explanation for human behavior.

Transportation, Land Use, and Environmental Costs

Transportation provides many benefits to society. As noted earlier, an efficient transportation system is critical to economic growth. People have benefitted greatly from cheap and efficient mobility. The value placed on mobility is revealed in willingness-to-pay: people devote a significant portion of their expenditure to transportation, about 18% in the US (US Bureau of Labor Statistics, http://www.bls.gov/cex/). However, mobility generates an array of environmental costs, notably air and noise pollution, traffic congestion, accidents, damage to the natural environment, and most seriously global warming. The transport sector accounts for 28% of US and 13% of global-green house gas emissions (US Environmental Protection Agency, http://www.epa.gov).

In addition, the benefits of mobility have not been realized by everyone. Those without access to a private vehicle, for example, have suffered a relative decline in accessibility as

activities have dispersed and public transport has become an increasingly poor substitute for the car. Concerns about these external costs are intensified by observation of current trends (Figures 2 and 3) and forecasts of global car ownership. Given current understanding of global climate change impacts, it is evident that policy actions must be taken to move toward a sustainable transport system. However, the question is what constitutes a sustainable transport system. Sustainable transport has many dimensions. Strategies range from improving transport technology to smooth traffic flow to reducing private vehicle travel via regulation, pricing, or land-use policy.

Transport geographers have focused on land use. The relationship between accessibility and travel is well known. Some geographers make a distinction between accessibility and mobility (e.g., Hanson, forthcoming). Accessibility measures potential – the relative location of opportunities – and is a function of spatial form and transportation supply. Mobility measures outcomes – how much a person travels. Mobility is a function of both accessibility and travel resources. It follows that as accessibility increases, activities can be conducted with less travel, all else equal. It is therefore argued that one promising strategy for sustainable transport is to promote higher-density development. Proponents argue that such a strategy preserves accessibility while reducing overall travel: activities can be accomplished closer to home, and shorter distances may allow more nonmotorized travel.

Increasing development density as a travel reduction strategy may have limited effectiveness. Total distance traveled is inversely related to density, but the relationship is of small magnitude: a unit increase in density yields a much smaller decrease in travel. For example, a recent US study estimates that if 75% of all new developments are built in a compact fashion (double existing density), and if residents drive 25% less on average in such developments, vehicle miles of travel, energy use, and carbon emissions would decrease about 8–11% by 2050 (TRB, 2009).

Higher density is also associated with congestion and slower travel speed, which may have a negative effect on energy use/emissions. Therefore, the net positive effect of density is unclear. Some have argued, however, that the proximity effect dominates (Levine et al., 2012), but it is important simultaneously to reduce traffic generated at or attracted to dense areas to counter the congestion effect (Melia et al., 2011). The way to reduce traffic is to provide viable alternatives and/or reduce inefficient auto travel by pricing or regulatory mechanisms.

Expansion of public transport infrastructure has become a key policy priority, since transit is seen as less damaging to the natural environment and as contributing to urban quality of life. Effective public transport depends upon concentration. Many argue that the presence of transit will promote higher-density development (e.g., Newman and Kenworthy 1998; in the presence of a favorable policy environment.

Transit and nonmotorized travel are facilitated by appropriate infrastructure. It is argued that sidewalks and bike lanes along with supportive urban designs and integration with public transport can complement existing pro-environment initiatives (e.g., Pucher et al., 2010). Interestingly, the extent to which such interventions can reduce transportation-related energy use and air pollution remains uncertain (Brand et al., 2014).

Long-term economic and technological trends suggest continued decentralization, dispersion, and increasing demand for private vehicle travel as per capita income grows in currently less developed countries (e.g., Muller, 2014). Hence some argue that environmental costs must be addressed via technology (e.g., better fuel efficiency, electric- or solar-powered cars, etc.), pricing, and regulation. Pricing and regulatory policies that directly affect private vehicle owners and users are often considered to be more equitable and economically efficient. Implementation of and reforms in car-ownership taxes, fuel taxes, parking charges, tolls, and congestion or road user charges are most common (Bonsall and Willumsen, 2014). However, such interventions are often politically unpopular. The challenge is to find the most effective method for achieving environmental goals. The social and environmental consequences of not reversing current trends are enormous, and it is assumed that the political will necessary to achieve major change will be found.

Transportation and Information Technology

Rapid advances in ICTs, through affordable mobile devices, connections, and applications, are an increasingly important theme of transport research. ICTs are changing travel patterns, firm locations, and the movement of freight. People can now access multiple activities at the same time (shopping while working and working while shopping) and access activities, goods, and services without travel. Transport geographers have been investigating how ICTs modify or promote travel through concepts of fragmentation, fixity, and flexible workplace practices.

The combination of increased fragmentation (breaking activities into subtasks), reduced fixity (tying activities to specific times and places), and flexible work practices (such as temporary work or self-employment) has enormous implications for travel behavior. It is possible, for example, that trip frequency will increase (fragmentation effect), and peak travel will decrease (flexibility effect). Figure 4 below plots the average frequency of trips taken by time of day for workers who have the option to work at home versus those who do not. On average, workers who have the option to work at home start their work trips later than the rest of the population. They also make more personal trips throughout the day, while those without flexible workplace options tend to cluster personal trips at the end of the workday. Effects on travel distance or mode choice are uncertain. Research on these issues is just beginning.

ICTs and their networking capabilities are also creating a new generation of transportation alternatives. Within the past decade Web-based taxi services, car sharing and ride-matching services, bicycle-sharing systems, and point-to-point intercity bus services have emerged. It is too early to observe how these services may affect travel, but such alternatives may reduce car ownership demand as travel by other means becomes more convenient.

The impacts of ICT on firm location and on the structure of production also have enormous implications for transport. Restructuring is characterized by outsourcing, customized production, flexible production, and just-in-time management of production, and distribution. The emergence of spatial

Figure 4 Distribution of trips by time of day and option to work at home. (a) Panel A: Average distribution of work trips individuals who are allowed the option to work at home (WAH) versus individuals who are not allowed the option (NWAH). (National Household Transportation Survey, calculated by Rhoads.) (b) Panel B: Average distribution of personal trips by individuals who are allowed the option to work at home (WAH) versus individuals who are not allowed the option (NWAH). (Source: National Household Transportation Survey, calculated by Rhoads.)

production networks implies increased goods movement and growing dependence on an efficient global transport network.

ICTs have large implications for the freight industry. Globalization has increased the complexity and competition of freight operations, and ICTs provide tools to enhance the effectiveness and efficiency of freight operations; empirical research on adoption and performance is limited, however (Perego et al., 2011).

Time/space compression is bound to increase as the boundaries between transportation and communication erode. Indeed, ICT calls into question the very notion of accessibility as an essentially physical concept (Hodge and Janelle, 2000). The direct and indirect effects of ICT will be a major area of future research in transport geography.

Abstract

This article provides an overview of transportation planning – an interdisciplinary field of research and practice that informs and supports decision making for improving the movement of people and goods that is essential for efficient economic production and effective social interaction. It introduces the readers to the basic concepts, frameworks, and analytical tools. Drawing primarily upon experience from the United States, it also briefly describes the field's evolving focus from mobility to accessibility, livability, and sustainability. The article ends with a discussion of the coming challenges and opportunities for transportation planning.

Transportation planning is a field of research and practice that informs and supports decision making – at both strategic and operational levels – for mobility and accessibility improvements. Building national highway and rail networks to stimulate economic growth, developing high-density cities with convenient public transit to reduce automobile dependence, promoting flexible work schedules and telecommuting to relieve peak-hour traffic congestion, and adopting fuel and congestion taxes to lower the vehicle-miles traveled (VMT) are examples of strategic decisions. Siting airports, railway stations, freeway interchanges, and bus lines and terminals; providing additional park-and-ride facilities; extending bike lanes and expanding bike share programs; and setting user fees for high-occupancy toll (HOT) lanes are examples of decisions at the operational level.

The main functions of transportation planning are to establish the linkages between transportation and the goals of a community (such as a city or a region) or an organization (such as a government agency or a private firm); forecast future movements of people, goods, and ideas between geographic locations; evaluate alternative approaches to facilitate these movements; and inform stakeholders of the likely economic, social, and environmental consequences of the choices. The analysis and evaluation often employ empirical data and quantitative methods, and are guided by the fundamental principles of efficiency, equity, and, increasingly, livability and sustainability.

The growth and evolution of transportation planning have reflected the changing demographic, economic, social, institutional, and technological characteristics of society. In the 1950s and much of the 1960s, transportation planning placed its primary emphasis on developing conceptual frameworks and analytical tools to support the construction of highways to accommodate the fast growth of populations, economies, and metropolitan areas and the rapid increase in automobile use (Meyer and Miller, 2001). Since the late 1960s, various social and environmental issues have become major concerns in transportation planning, and the efficient use of existing infrastructure, reduction of environmental impacts, and creation of livable cities have become important societal goals (Meyer and Miller, 2001). In particular, since the late 1990s, increasing awareness of global climate change and its strong connection with greenhouse gas (GHG) emissions from automobiles has placed sustainability at the center stage of transportation planning (Cervero, 1998; Newman and Kenworthy, 1999; Banister, 2002). Reflecting the diverse concerns and shifting emphasis, many new ideas and approaches have emerged in this field over the last four decades.

As the world becomes increasingly urbanized, new challenges and opportunities for transportation planners are mostly found in cities. Furthermore, transportation planning is especially needed in large urban areas where human activities are highly concentrated, and where spatial interactions among individuals and organizations are highly intensive and complex. Therefore, urban transportation planning has been, and will continue to be, the most active area of this field.

Basic Concepts and Frameworks

Transportation planning is an *interdisciplinary* field that has multiple intellectual roots. Like any other field, transportation planning employs many concepts and frameworks. These concepts and frameworks are from diverse sources, including the academic disciplines of planning, engineering, economics, and geography.

Transportation is closely tied to the concept of *mobility* – the ability to move people and goods from one location to another quickly, safely, and cost-effectively. Travel speed, road capacity, transit service frequency and reliability, the resulting time savings, and the resulting volumes of people and freight transported are among the common measures of mobility. High mobility is generally desirable, but should not be seen as the ultimate goal for planning and decision making. This is because the movement of people and goods is rarely an end in itself; rather, it is a means to achieve certain goals of individuals, organizations, and communities. Going to work, meeting friends, increasing labor productivity, manufacturing products, supporting economic development, and improving livability are examples of goals for which transportation serves as a means.

Once the goals associated with movement are taken into consideration, transportation is most fundamentally about

providing *accessibility*, which refers to the ease of reaching spatially distributed economic and social opportunities. The most basic mathematical expression of accessibility is the summation of spatially distributed opportunities weighted by the corresponding impedances, which measure the effect of travel distance, time, or monetary cost. Accessibility is a function of both *the transportation system* and *the activity system* that is usually characterized by land use. Increasing mobility is only one possible way to improve accessibility; shortening travel distances to destinations (i.e., proximity) and enabling remote interactions via the Internet or other electronic means are other possible ways (Levine et al., 2012; Shen, 2000). Focusing narrowly on the transportation system would be a partial and unsatisfactory approach to transportation planning.

Closely related to the notion of transportation as a means for participation in economic and social activities, transportation is *derived demand* in that its utilities come from the activities in various locations accessed via travel, not from the travel itself. In fact, with the exception of occasional driving for fun and biking and walking for recreation, transportation involves disutility in the form of time spent, in addition to monetary costs, safety risks, and discomfort. The *generalized travel cost* represents the sum of these various forms of disutility. Conceptually, transportation demand can shift because of changes in the activity system or in travel cost. The former is fundamentally determined by the level, location, and other characteristics of economic production and social interaction. The latter is primarily a function of transportation service quality, capacity, and price. Technology is often the key driving force behind dynamic changes in transportation demand and supply.

For participation in a given set of activities, individuals (and organizations, such as firms) will choose the *transportation options* that minimize their generalized travel costs. A transportation option is some combination of travel modes, routes, and schedules. Individuals with different socioeconomic, demographic, and lifestyle characteristics tend to find different options to be the best choice. For example, high-income professionals tend to place higher opportunity costs on travel time and hence prefer driving alone, whereas low-income workers and senior citizens tend to take public transit for, respectively, financial and health reasons. Similarly, different firms often choose different transportation options for shipping inputs and products. This diversity in demand provides the fundamental economic rationale for developing *multimodal transportation*. It also relates to many social equity issues that must be addressed in transportation decision making. Historically, advances in technology and restructurings of the economy have continuously redefined the available transportation options, which have recently added various combinations of telecommuting, teleshopping, telesocializing, and travel in physical space.

Individuals' rational transportation options, however, are not always preferable from the viewpoint of the society as a whole. This is because the *private cost of transportation* is often different from the *social cost of transportation* due to market and policy failures. In the United States and many other parts of the world, excessively large percentages of people choose to travel by private automobiles because the costs borne by them do not fully account for the *environmental and social externalities*. The discrepancy between private and social costs of transportation fundamentally justifies transportation planning in the public domain.

Transportation planning is an integral part of transportation decision making that takes place within an *institutional framework* consisting of special government agencies, service providers, participating organizations, community and interest groups, formal and informal interactions among these entities and people, funding mechanisms, and relevant laws, regulations, and norms. The composition and characteristics of the institutional environment largely define the transportation planning and decision-making process. Because the institutional environment is dynamic, the transportation planning and decision-making process also changes over time.

In the United States, transportation decision making in the 1950s and 1960s was based on the rational planning model (Meyer and Miller, 2001). The *rational planning process* typically included the key steps of defining goals and objectives, generating alternative approaches, evaluating alternatives, selecting an optimal alternative, and implementing the chosen alternative. Since the 1970s, *alternative planning models*, such as incremental planning, advocacy planning, and communicative planning, have been adopted in various contexts of transportation decision making. The application of these alternative planning models, often to complement rather than replace the rational model, reflects increasingly pluralistic values, diverse interests, complex organizational and power structures, acute awareness of environmental and financial constraints, and better understanding of uncertainties. It also reflects the growing sophistication of transportation planning as a field.

A systems perspective is effective for conceptualizing transportation planning problems and examining transportation impacts (Meyer and Miller, 2001). Transportation can be viewed as one system that is a component of numerous systems, such as the economic system and the ecological system. It interacts with many other systems, such as land use, energy, telecommunications, demographics, and social relationships. The transportation system itself is composed of subsystems, including users, modes, networks, facilities, and services, which are interconnected. Key concepts of systems theory have found useful applications in transportation planning (Meyer and Miller, 2001).

Analytical Tools

Transportation planning is also an *applied* field that relies on some standard tools to perform its functions. Many of these tools are analytical methods adopted from other fields. Examples are (1) statistical analysis of travel survey data, which applies methods developed in mathematics and statistics; (2) visualization and spatial analysis of transportation networks, facilities, built environments, peak and off-peak distributions of trip origins and destinations, and traffic flows using geographic information systems (GIS) and associated tools that originated from computer science and geography; (3) evaluation of alternative transportation projects and plans by conducting cost–benefit analysis or cost-effectiveness analysis, which are commonly applied techniques of economic

analysis; and (4) assessment of air quality, noise, and other environmental impacts of transportation by employing models built by scientists and engineers.

Some analytical tools have been developed specifically for transportation planning, even though many researchers from other disciplinary backgrounds have contributed to the efforts. The most fundamental tool of this kind is the urban transportation modeling system (UTMS), also known as the *four-step travel demand model*, which was originally developed in the 1950s and 1960s to generate forecasts of future volumes of travel on highways and transit lines (Meyer and Miller, 2001). The four steps refer to (1) trip generation, (2) trip distribution, (3) mode split, and (4) trip assignment. In the first step, the region is subdivided into a large number of areal units called traffic analysis zones (TAZs). Then, trips by travel purpose (e.g., home-based work, home-based other, and nonhome-based) are generated for each zone. Trips are classified as either a production (the home end or origin of a trip) or an attraction (the nonhome end or destination of a trip). Linear regression models are typically used to predict trips generated in a zone. Models for productions often include the number of households in the zone, household size, income, and automobile ownership as independent variables, whereas models for attractions often include numbers of jobs and households in the zone as independent variables.

In the second step, a mathematical procedure – most commonly a gravity model – is used to link the productions and attractions among all zones, and distribute the trips from each production zone to each attraction zone. These zone-to-zone flows include commuting trips to workplaces and other trips for various purposes such as shopping, visiting friends, and going to entertainment and sporting events. In an analogous form of the physics law of gravitation, the model computes the flow of trips between each zone pair based on the total number of trips produced in the origin zone, the total number of trips attracted to the destination zone, and travel impedance for going from the origin to the destination. Everything else being equal, the flow of trips from an origin zone to a destination zone increases with the total numbers of productions and attractions but decreases with the travel impedance.

In the third step, the predicted flows of trips are divided among available modes, such as drive alone, carpool, public transit, bike, and walk. Modal split is determined by the characteristics of competing modes such as speeds and costs; the characteristics of travelers such as income, automobile ownership, and age; as well as the characteristics of the trips themselves such as the trip purpose and the built environments of the origin and destination. Alternative methods have been developed to predict the percentage of trips using each available mode. Today, this procedure is typically accomplished by employing some kind of discrete choice model – most often the multinomial logit model – that computes the probability of choosing each mode.

In the final step, the predicted flows by mode are assigned to highway and transit networks. There are alternative computer algorithms for trip assignment, including minimum path assignment, various forms of user equilibrium assignment, and system optimum assignment. These alternative methods are based on different assumptions and, therefore, are suitable for different application contexts. Minimum path assignment, which loads all trips from any origin zone to any destination zone onto a single lowest cost path, is unreasonable except in the rare case where traffic is sparse, networks are uncongested, and alternative routes are highly differentiated in terms of travel cost. User equilibrium assignment, which generally assumes that each traveler chooses the perceived optimal route, is the more realistic approach. In contrast, system optimum assignment, which aims to minimize the overall congestion by informing and influencing travelers' route choice, is not behaviorally realistic but useful for improving the efficiency of existing networks.

For over half a century, the four-step travel demand model has been widely applied, especially to urban transportation planning in large metropolitan regions. While robust and long lasting, the model has been criticized for its various shortcomings (Banister, 2002). The four-step technical process is based on the rational model of planning and decision making, which has its limitations in dealing with problems involving diverse values and major uncertainties. In addition, it is built upon a weak behavioral foundation and relies primarily on empirical relationships to predict changes. Furthermore, it has a strong orientation toward promoting more and faster travel as the solution to transportation problems.

Researchers have effectively responded to some of the criticisms of the model. In particular, since the 1970s, *discrete choice models* based on the random utility theory have been incorporated into the modal split procedure of the traditional four-step model. Discrete choice models, developed by Domencich and McFadden (1975), Ben-Akiva and Lerman (1985), and others, model the decision making of individual travelers. The underlying assumption is that an individual traveler will choose an alternative that appears to maximize the utility. Recognizing that people do not always choose the objectively best option or make consistent choices over time, the utility function consists of two components: (1) the systematic and observable component that is identical to the conventional economic utility function, and (2) a random component that is used to capture variations in perceptions among individual travelers, as well as model specification and data measurement errors. The systematic component of the utility for an individual is a function of the attributes of each alternative and the characteristics of the individual.

With the random component included, the utility function does not determine which alternative is definitely the best for an individual, but enables the calculation of the probability that a given alternative will be chosen from the available choice set by an individual who has certain characteristics. The probability can have different functional forms based on different assumptions about the statistical distribution of the random component. The commonly used logit model results from an assumed Gumbel distribution of the random term.

The development of the discrete choice models has significantly advanced travel demand analysis by strengthening its behavioral foundation. Although modal choice has been the main area of application, discrete choice models have been employed to examine many other transportation decisions, including automobile ownership, trip destination choice, and residential location choice.

Almost in parallel, over three decades of research efforts have been made to develop *activity-based models*, which predict travel demand by focusing on people's participation in activities, such as working, shopping, and recreation. These models incorporate the time–space geography framework originated by Hägerstrand (1970), which conceptualizes the opportunities for, and constraints on, activity participation by individuals with various locational, demographic, and socioeconomic characteristics. Travel is derived from daily activities undertaken by households and individuals, and these activities are spatially distributed but temporarily sequenced and bounded. In addition to the activity-based framework, these models typically incorporate the tour instead of the trip as the basic unit for travel demand analysis, and apply microsimulation techniques at the disaggregate level of households and persons to convert activity and travel choices into a series of discrete decisions (Davidson et al., 2007).

The activity-based approach has several distinctive strengths that do not exist in the four-step modeling framework. It is highly disaggregate in representing the travel behavior of each individual and household, which helps it avoid the errors associated with generalization and lend itself to a more realistic and accurate portrayal of travel behavior. It explicitly models the relationships between an individual's different activities (e.g., work and nonwork), as well as the interactions between household members. These capacities, together with detailed information about activities and travel segmentation, substantially broaden the range of transportation planning and policy issues that the models can help address. For example, activity-based models can more realistically assess the effect of implementing high-occupancy vehicle (HOV) lanes by accounting for intrahousehold travel decision making. Another example of a useful application of activity-based models is to examine the amount of travel reduction resulting from telecommuting, which may redistribute some component trips (e.g., dropping off the kids at school on the way to one's workplace in the morning and shopping for groceries in a supermarket on the way back in the afternoon) of the preexisting commuting tour to other time windows.

Activity-based models also have shortcomings: they are more complicated and, therefore, the development cost is much higher; they require the collection of disaggregate travel diary data that are more complete and accurate in identifying household interactions as well as individuals' activities, which is a high expectation not easily met through home interview surveys. Furthermore, there are still some challenging theoretical and technical issues that need to be addressed in future research (Davidson et al., 2007).

Activity-based models have recently become viable alternatives to four-step models for a variety of applications. In the United States, a number of metropolitan areas, including New York, San Francisco, Denver, and Portland, are now using activity-based models for transportation planning. Several other metropolitan areas, including Chicago, Seattle, and Houston, are currently developing models of this type. Activity-based models have also been developed and applied in several European cities. However, the practical – not just the theoretical – advantages of the activity-based approach must be more clearly demonstrated before it can be widely adopted for travel demand modeling.

Another important technical tool, which produces required data for long-range travel demand analysis, is the *land use model*. Since the movement of people and goods is derived from the economic and social activities in which they participate, or to which they contribute, the quantities and locations of residential, employment, commercial, service, and recreational activities must first be measured or predicted before the demand for transportation is analyzed. Understanding and modeling the activity system are especially critical for the long term because it cannot be assumed to remain the same. Land use models serve as an essential tool for depicting likely future changes in the activity system as a basic input for forecasting future travel demand. At the same time, these models also provide the capacity for assessing the likely short-term and long-term impacts of proposed changes in the transportation system on the activity system.

Urban modeling, a field of research focusing on building land use models for urban areas, has been active for over half a century, although its development certainly did not follow a smooth upward curve. In general, these models make conditional predictions of land use changes in a city or metropolitan region in accordance with changes in the economy, employment, and population. The models either explicitly or implicitly incorporate both the market mechanisms for, and the policy constraints on, urban land allocation. Accessibility and other attributes are evaluated for each land unit (e.g., a parcel or a grid cell), and available land units are allocated to competing users (e.g., firms in different economic sectors and households with different socioeconomic characteristics) who place different utilities on these attributes.

Despite the fundamental importance of accessibility and spatial interaction in land use models, in the United States the analysis of the activity system proceeded essentially independent of the analysis of the transportation system for decades. That was primarily because, institutionally and professionally, different agencies and people were responsible for the respective tasks (Meyer and Miller, 2001). Since the early 1990s, however, the connection between land use and travel demand analyses has been greatly strengthened. Recognizing the effects of transportation on land use and the environment, the 1990 Clean Air Act Amendments and the 1991 Intermodal Surface Transportation Efficiency Act both required metropolitan planning agencies to integrate land use and transportation planning (Meyer and Miller, 2001; Waddell, 2002). Additional pressure for this integration has come from state programs for growth management that promote a stronger linkage of land use and transportation planning, as well as from concerned researchers, practitioners, and environmental advocates (Waddell, 2002).

Today, in various parts of the world, operational models are employed to produce land use and travel demand forecasts by accounting for the interactions between the two systems. Some of these models are *integrated land use and transportation models*, which represent the interactions between land use and transportation within a unified model of activity and transportation systems. Others are separate but loosely coupled models of

land use and travel demand that feed each other with outputs (e.g., jobs and households from the land use model, and modal shares, travel times, and travel costs from the travel demand model) for future years. In either case, the dynamic relationship between land use and transportation – for instance, improved accessibility in an area attracts more firms and households to locate there, which in turn can cause traffic congestion, lower accessibility, and discourage further growth – can be captured.

Evolving Focus from Mobility to Accessibility, Livability, and Sustainability

The most basic function of a transportation system is to increase mobility, but the true economic value of mobility is not realized until it effectively connects people and goods to their desired destinations. Therefore, while mobility is the most distinctive property of a transportation system, accessibility is conceptually the more appropriate measure of its performance (Levine et al., 2012). As livability and sustainability become primary goals for a growing number of countries, regions, and cities, accessibility will increasingly become the main focus of transportation planning. In a world with finite resources but growing needs, transportation planners are responsible for helping improve quality of life by increasing accessibility while avoiding irreparable damage to the environment by restraining travel-related energy consumption and emissions.

Despite the clear advantage of emphasizing accessibility over mobility, in most parts of the world enhancing mobility used to be, and in many cases continues to be, the primary goal for transportation planning. In the Unites States, for almost half a century after World War II, transportation planning aimed principally at building highways to accommodate private automobiles. While it certainly achieved many positive results, including higher economic productivity and speedier travel for the great majority of the population, it also generated various undesirable consequences. Traffic congestion, lack of adequate public transit service and bike and pedestrian facilities, and degradation of old urban neighborhoods have been some of the negative outcomes (Cervero, 1998). In addition, the automobile-oriented mobility enhancement has resulted in a huge accessibility gap for those who depend on public transit (Shen, 1998).

The United States has become the world's most automobile-dependent country: the number of vehicles per capita is about 0.8; and 76% of commuters drive alone, whereas barely 4.9% of them take public transportation (Davis et al., 2012). This high level of automobile dependency poses major challenges for energy security and environmental sustainability: with less than 5% of the world's population, the United States consumes about 22% of global petroleum production and generates about 20% of total carbon dioxide emissions, and the transportation sector accounts for approximately one-third of its carbon emissions (Davis et al., 2012).

Continuation of mobility-focused transportation development would contradict the global trend of sustainable development. Although the awareness of certain negative environmental and social consequences of automobile dependency has existed for decades, the real wake-up call came in the 1990s with the understanding of climate change and its strong connection to transportation. The adoption of the Kyoto Protocol in 1997 marked the beginning of a new era of transportation planning in the United States, as well as in many other countries. Reducing GHG emissions has become a key objective not only for automobile manufacturers and energy suppliers, but also for transportation planners. This is because, for the foreseeable future, more efficient vehicles and lower carbon fuels will not effectively mitigate GHG emissions unless people reduce their motorized travel (Hankey and Marshall, 2010).

By shifting focus from mobility to accessibility, and by setting livability and sustainability as the ultimate goals, transportation planning has opened up to new ideas and incorporated new approaches. Most importantly, land use is no longer taken as a given, but seen as a means for achieving the goals by modifying the patterns of activity participation and travel. New urbanism design guidelines, smart growth principles, and transit-oriented developments (TOD) have become widely accepted land use measures for reducing automobile use and encouraging transit use, biking, and walking. There have been many other significant changes, including a stronger emphasis on transportation system management and demand management, wider applications of technology (e.g., telecommuting and real-time transit information), more complete cost accounting in transportation pricing, and deepened concerns for social equity and environmental impact (Meyer and Miller, 2001).

More opportunities have been created for new and exciting research in transportation planning. For example, a large number of publications have been added to the literature on the travel behavioral effects of land use initiatives (Ewing and Cervero, 2010). Vigorous research activities have also been seen in important topic areas of travel demand management, including parking charges, congestion pricing, and mileage-based fuel taxes. In addition, solid efforts have been made to shed new light on the viability and values of transportation alternatives. For example, real-time transit information accessible through mobile phones creates new possibilities to make public transportation more attractive and competitive (Watkins et al., 2011). Another example is the sudden surge of research interest in nonmotorized transportation, which has obtained encouraging findings of measurable health benefits from biking and walking.

The new era has also witnessed significant changes in the practice of transportation planning. Travel demand models and land use models have become more integrated (Waddell, 2002). Numerous development projects that follow the guidelines of new urbanisms and TOD have been implemented, and smart growth principles have been adopted by many planning agencies in the United States and beyond. More carpool and bus lanes have been created, and more bicycle facilities have been built, in many cities. Parking regulations have been modified by many local governments. These are just a few examples of the encouraging changes.

Challenges and Opportunities for Future Research

Transportation planning, which is essential for well-informed decision making on infrastructure, services, and policies for overcoming spatial barriers to economic and social activities,

will continue to be a vibrant field in the future. To play its role effectively – in particular, to help cities and regions build appropriate connections between their mobility and accessibility improvement strategies and their livability and sustainability goals – transportation planning must continue to advance knowledge. There are major knowledge gaps, including the following, which present both great challenges and opportunities for future research.

First, there is *confusion over the effect of land use change on travel behavior*. A large volume of research on this topic has so far generated inconsistent findings. Most of the empirical studies based on intrametropolitan data have identified a statistically significant relationship between land use and travel demand, but suggested a rather modest effect as shown by the low elasticity values (Ewing and Cervero, 2010). Much greater effects, however, are seen by comparing cities or metropolitan areas using aggregate data on density and per capita energy consumption (Newman and Kenworthy, 1999; Glaeser, 2011). What do these inconsistent findings imply regarding the relationship between the activity system and the transportation system? Conceptually, land use change, such as densification or diversification, directly alters only some physical aspect of the activity system. It may have little impact on individuals' current pattern of activity participation, and hence their short-term travel behavior remains unchanged. The challenge is to reconcile the generally weak short-term effects and the much stronger cumulative effects. In addition to land use change, what other factors may trigger substantial adjustments in people's spatial and temporal arrangements of activities? Implementation of complementary governmental policies such as congestion pricing and mileage-based fuel tax, provision of convenient and safe transit and nonmotorized options, formation of new societal norms, and change of individual values are all possible factors for future investigation.

Second, there is currently *a lack of systematic research effort to support planning for alternative transportation modes*. Although there are recent empirical studies on various issues concerning public transit and nomotorized travel, they do not serve as a consolidated foundation for reenvisioning the alternative modes. For example, several studies have identified important economic and psychological benefits brought to transit riders by real-time bus arrival information systems (Zhang et al., 2008; Watkins et al., 2011), and many research projects have recently been undertaken to show the health benefits associated with walking and biking. These efforts, although offering useful insights, do not provide sufficient information to address transportation planning questions such as whether or not public transit will become a viable option for suburban residents, and whether or not adding hundreds of miles of bicycle lanes to the existing street network will produce enough benefits to offset the costs.

Third, there is *rather limited understanding of the likely impacts of technologies* on the transportation system, the activity system, and their interrelation in the foreseeable future. Major breakthroughs in automotive and fuel technologies could dramatically reduce oil dependence and GHG emissions, and significantly improve the sustainability prospect of the transportation system. Although future advances in these technologies are uncertain, transportation planning will be more informative if it can draw from careful analyses of alternative scenarios and implications.

Similarly, information and communications technologies (ICT) have started to demonstrate their huge capacity to modify the patterns of activity and transportation of individuals and organizations, but the implications for transportation planning are not clear. Transportation researchers tend to concentrate their analysis on the direct and short-term effects of ICT in the forms of travel substitution, generation, and reconfiguration (Mokhtarian, 1990). The longer term secondary impacts on the transportation system through relocations of residence and activities are insufficiently investigated (Shen, 2000). Perhaps more critically for livability and sustainability, timely efforts should be made to understand how future developments in ICT may provide individuals and organizations with an adaptive ability, so that they can maintain their basic economic and social functions while adjusting their spatial and temporal configurations of activities at a relatively low transaction cost.

Fourth, transportation planners *must learn to incorporate uncertainty explicitly into the planning process*. The future is always unknown, but the level of uncertainty, and hence the risk, is especially high when the decision making is about a major project or policy that has long-term livability and sustainability consequences. High-level uncertainty is quite common in planning and decision making, but for decades transportation planning managed to largely follow the rational planning process (Banister, 2002). Given its strong relationships with the future well-being of human society, on one hand, and with dynamic technological forces, on the other hand, the transportation system should be planned with a clear understanding of the assumptions, uncertainties, and complexities involved. In addition, it will be critical to devise mechanisms to support 'incremental but informed planning' by continuously monitoring technological, economic, social, and behavioral changes over time, and by promptly veering onto another course if future events make that necessary (Wachs, 2012).

Finally, with a rapidly growing population and economy, and rising levels of automobile ownership, *developing countries are the new frontier for transportation planning research and innovation*. Because the majority of the world's population reside in these countries, future changes in their travel behavior will have a profound implication for sustainability. The transportation sector currently accounts for a lower percentage of the total GHG emissions in developing countries, but it is increasing rapidly with the expansion of the car-owning middle-class population (Dulal et al., 2011). For example, China has recently become the world's top country in vehicle sales, and its annual vehicle growth rates for the next 10 years are projected to be around 10%. Fast-paced motorization and urbanization in developing countries present a highly challenging yet rewarding task for transportation planners: to help achieve livability and sustainability goals by helping reshape the mobility and activity systems. What do they need to study to prepare themselves for this huge responsibility?

The above list is far from exhaustive; one could add many more future challenges and opportunities, ranging from improving travel demand models to reforming transportation planning institutions. But the list is sufficient to illustrate the

variety of important problems that will continue to make transportation planning an exciting, and hopefully fruitful, field for the foreseeable future.

Abstract

The psychology of transportation entails the study of human behavior and well-being in conjunction with the regularized movement of people, goods, and services regarding work, personal life, and community activity systems. It includes the interface of humans with transport system components, including their design and operation, provisions for human needs, forms of utilization, and social impacts, including public safety.

The psychology of transportation entails the study of human behavior and well-being in conjunction with the regularized movement of people, goods, and services regarding work, personal life, and community activity systems. The information age has radically modified both work products and the means of transportation, yet physical mobility on transport systems remains fundamental to our commerce, recreation, and other life-sustaining activities. The psychology of transportation also includes the interface of humans with transport vehicles and facilities, such as their design for optimal operation, provisions for human needs, forms of utilization, and social impacts, including public safety.

Overview and Scope

The domain of transportation has great relevance for psychology, precisely because of its salience in the routines of daily life and its importance for meeting personal, family, and organizational goals. Correspondingly, because components of transport systems are operated by people, psychology has an important role in system development, efficiency, and safety. Human cognitive, personality, and performance factors affect vehicle operation. Recognition of the intrinsic value of psychology produced the launching of a new section of the Transportation *Research* journal devoted to psychology and behavior, which opened with the article by Groeger and Rothengatter (1998).

Transport systems shape the structure of our communities and have a significant impact on both personal and community well-being. For example, urban sprawl, with its low-density land use and automobile commuting dependence, has public health impacts associated with air pollution, motor vehicle crashes, and psychological stress (Frumkin, 2002). Workers' average daily commuting time varies substantially across countries, ranging from about 15 min in Finland and New Zealand to about 40 min in Korea and Japan, with the United States and United Kingdom being around 25 min (Organization for Economic Co-Operation and Development, 2013; Pisarski, 2006). Within countries, there is, of course, much regional variation, such as in the United States where metropolitan area commute time averages range from 14 to 35 min (United States Census Bureau, 2011).

Personal well-being and the progress of human societies have always been associated with mobility and transportation. People respond to environmental constraints on mobility and strive to enhance well-being. However, the mobility and well-being relationship is not uniform, as higher levels of travel may be reflective of constraints on opportunities, depletion of resources, and impairments to personal health and job performance. What happens on a particular journey depends on many intertwined psychological elements, including personality disposition, attitudes about the origin and destination of the trip, and resources for choosing alternative travel modes and schedules, including telecommuting. Working at home has been the fastest growing commuting mode from 1980 to 2010, while carpooling has steadily declined (Pisarski and Polzin, 2013). There is thus a vast terrain for psychological research and application of psychological knowledge. The creation and use of transportation systems, the experience and behavior of people in transportation conditions, and the effects of mobility constraints on personal and community health are important areas in the psychology of transportation.

Human factors have long been recognized as being important to vehicle operation, most certainly heightened by the application of science to warfare. However, the psychology of transportation in civil society is much broader in scope than the interface between the human operator, the vehicle, and the road design or rail system (Rothengatter and Vaya, 1997). It entails travel mode decisions, driver attitudes and performance, the interplay between work and family, emotional well-being, and major societal issues, such as the needs of special populations, the definition of the workplace, the provision of transportation facilities, and travel safety.

The field of transportation has been dominated by engineers, urban planners, and economists; but the contributions of psychologists and sociologists integrated into this arena for decades (e.g., Altman et al., 1981; Stokols and Novaco, 1981; Wachs and Crawford, 1992). Discussions of the social costs of transportation are now common, and psychological elements are given weight in such considerations. Because individuals, families, and work organizations recognize that they absorb hidden costs associated with traffic congestion, air pollution, and traffic noise, psychological science is important for understanding how to optimize transportation systems and to assess the consequences of travel strains.

One area where psychology's impact on the transportation field has grown substantially is public safety, particularly with regard to driving behavior. Interest in this domain has expanded from traditional work on unsafe driving associated

with fatigue, substance use, driving histories, aging, and risk-taking tendencies to include developmental issues associated with younger and older drivers, specialized attention to personality styles, motor vehicle accident trauma, antisocial behavior on public transport, driver education, and problem-targeted intervention programs. Gossling (2013) has suggested that 'clinical transport psychology' be developed as an area. There is now bountiful literature on 'aggressive driving' (e.g., Galovski and Blanchard, 2004; Shinar and Compton, 2004) and various instruments to assess 'driving anger' (e.g., Deffenbacher et al., 2002; Sullman and Stephens, 2013). Although far less extensive as that in the personality/emotion domain, the study of psychological trauma associated with motor vehicles accidents (e.g., Mayou et al., 2002; Wiesenthal and Vingilis, 2013) is an important and rich area for research, particularly given the high prevalence of vehicle crashes.

Historical Development of the Field

Involvement by psychologists in the field of transportation began in the 1920s when transport companies and government agencies sought to improve the selection of drivers of public transport vehicles, and psychometric testing became used in choosing the operators of buses, trams, and trains. A central concern was to minimize accident risk, and psychological tests were used to screen applicants who could be anticipated to be accident prone. Wartime studies of adjustment among military personnel and the early psychological formulations of stress, adaptation, and coping that resulted from observations made by psychological researchers working with the military extended quite nicely to the subject of driver performance demands and safety risk. As well, industrial psychology research on fatigue at the workstation transferred to the issue of vigilance in professional train and road drivers (Barjonet, 1997).

As the motor car progressively came to dominate travel in Western societies in the 1950s and 1960s, car ownership grew dramatically; accident rates and road deaths became serious public health problems. In most European countries, the number of road deaths doubled between 1955 and 1970, much worse than in the US Public safety policies, such as speed limits, penalties for drunk driving, and ultimately seat belts were instituted to curtail casualties, and research into the human causes of accidents came into play. Social psychological knowledge was used in public persuasion efforts, and theories and techniques of learning found fertile ground in driver education and rehabilitation. The advent of the computer augmented the capacity to analyze and integrate data, and understanding driver-based safety risk in the 1970s and 1980s often took the form of psychological modeling incorporating personal background, attitudinal, motivational, and emotion variables on top of ergonomics. That period is now overshadowed by twenty-first century technology of traffic management, collision warning, and collision mitigation systems.

The growth in automobile commuting that occurred between 1960 and 1980, especially in the United States, prompted interest in modeling how trips were generated, how they were distributed across travel zones, and how trips split across available transportation modes (car, bus, train). The boom in automobile commuting followed from substantial growth in the number of jobs, in the working age population, and in the number of women in the labor force. In addition, homes and jobs shifted to suburban locations. Because neither highway nor transit systems were designed for suburb-to-suburb commuting, traffic congestion in metropolitan areas became a salient issue. In the United States, the use of private vehicles between home and work nearly doubled from 43 million users in 1960 to 83 million in 1980. At the same time, alternative modes of travel declined, vehicle occupancy declined, and national investment in highway infrastructure fell far behind the demand for road use (Pisarski, 1987). The suburbanization trend continued in the 1990s, with more than 50% of commuters in the 2000 census being suburban residents, and suburb-to-suburb commuting grew 64% from 1990 to 2000 (Pisarski, 2006). Quite strikingly, carpooling declined each decade from 1980 to 2010 (Pisarski and Polzin, 2013).

Similar trends have occurred in Europe. Since 1970, 87% of the growth in the transport of people has occurred in the road passenger transport sector (European Commission, 2006). From 1970 to 2003, the automobile share of passenger travel increased from 74 to 79%, while the rail transport share declined from 10 to 6%, and the bus/coach share dropped from 13 to 8%. The information society has not reduced the need for mobility – a European citizen traveled 17 km a day in 1970 and that rose to 35 km three decades later, heightening concern about traffic congestion (European Commission, 2006). In Southeast Asia, mega-urban regions have immense public transport problems, with travel times to work of 2 h being normal, as is the associated lost productivity and poor quality of life (Jones, 2002).

European cities, with their treasured historic centers having limited road space and parking facilities, became concerned about the detrimental effects of traffic congestion and pollution and were keen to impose access restrictions and 'traffic calming' to reduce automobile use and safeguard pedestrians. These trends spurred interest in road pricing (Jones and Hervik, 1992) and individual travel behavior. Computer analytic methodology spurred travel demand modeling, which blended consumer theory in economics with choice theory in psychology, which assume that people use some utility or value function in assessing choice alternatives. Psychological variables continue to facilitate understanding of the use of priced managed lanes (e.g., Devarasetty et al., 2014) and switching to public transit (e.g., Chen and Chao, 2011).

Attention to the transportation needs of special populations, such as working mothers, the elderly, and those affected by physical disabilities, also came into focus during the 1970s and 1980s. An important component of the auto-commuting boom was a large increase in the number of women in the labor force (Grieco et al., 1989; Pisarski, 1987). Single women with children who lived in suburbs were very dependent on the automobile (Rosenbloom, 1992). In the United States, most trips made by working mothers and their children cannot be made by transit, and the impact of travel constraints on the quality of family life is an important topic. In the 1990s, telecommuting emerged, partly as a way to reduce strain on family life. The convergence of technological, economic, social, and psychological factors made work less

place dependent, and telecommuting was heralded as a viable alternative to auto commuting (Mokhtarian, 1990). From 1999 to 2012 in the United States, access to flexible workplace benefits (requiring a formal telework program) increased from 3% of all workers to 6% (Pisarski and Polzin, 2013).

The information age had many effects on transportation systems. The development of intelligent transport systems, such as in-vehicle navigation (route guidance and congestion warnings) and increased sophistication of driver panel displays, as well as mobile phone use and the intensification of information-based work demands, have raised the importance of driver control, visual search efficiency, and mental load on driving proficiency. Both legal sanctions and further technological developments are being guided by understanding psychological factors. On the horizon of advanced technologies are Intelligent Vehicle Highway Systems that automatically control speed, steering, and spacing. Psychological issues of personal control and freedom (long-standing themes intrinsic to car ownership and driving) and matters of privacy come to the fore with regard to having a vehicle under the control of a computerized system, GPS tracking of vehicle usage, or on-board video monitoring of driving behavior.

Human Factors and Driver Performance

Psychological variables affect the operation of vehicles, as can be seen in studies of driver error and performance decrements (cf Rothengatter and Vaya, 1997). Fatigue has been the most researched topic in this regard. Ordinarily understood as physical exhaustion, it can also involve boredom, task aversion, uncontrollable sleepiness, hypnotic trance-like states, or loss of alertness. Driving performance decrements occur before the driver is aware of the fatigue. Fatigued drivers become complacent and underestimate the effort needed to maintain driving performance. Hours of service limitations are implemented for professional drivers and pilots to guard against fatigue-related safety errors. Police officers must be trained to recognize fatigue. Armstrong et al. (2013) found that 19% of 1600 Australian drivers reported having nearly crashed while fatigued, and 2.4% did crash. Physiological correlates of fatigue have been studied in both driving simulator studies and open-road tests. Heart rate decreases with prolonged driving time, but results across studies have not been uniform. Focal fixation, detected by eye-tracking, is associated with fatigue, but that also occurs in conjunction with hazard perception.

Driver alertness is clearly related to collision avoidance. The driver, as an information processor, must be proficient in making time-to-collision judgments – for example, time to collision is underestimated for smaller vehicles. Generally, the more enriched the visual environment, the lower the underestimate of time-to-collision. Vehicle design modifications have been made progressively in rear brake signals and daytime running lights to reduce collisions, and road design features involving reflectors, warning signs to reduce speed on curves, and edge lines are intended to enhance the input of safety information. Major advances have been made in forward collision and lane departure warning systems, some of which take action autonomously.

Driver expectations and interpretations, however, interact with visual information. Expectancies developed from driving experience may have adverse effects. The person may omit perceiving relevant cues or fail to give them appropriate weight in estimating a hazardous condition. 'Driving experience' does not guarantee expertise, as an experienced driver may have fixed expectations about how a driving situation will progress, which may interfere with accurate perceptions and interpretations of relevant cues. Driver behavior is a function of what drivers believe and feel they can do, as well as what they see and are told.

The topical salience of driver distraction has been intensified by the information age as the use of portable devices for information, communication, and entertainment have infiltrated the psychological space of vehicle operations and have been attributed to be the cause of crashes of cars, trucks, busses, and trains. Text messaging is more impairing than is cell phone usage, and it is a prevalent problem among teenage drivers. Media-based campaigns (as occurred regarding seat belt use) aiming to inform, persuade, and motivate the public to change attitudes and behaviors to improve transport safety are an important domain for the application of social psychological knowledge and behavioral modeling.

Driver Risk Taking, Attitudes, Motivation, and Emotion

The study of driver performance lends itself to experimental lab analyses of perception, decision-making, and reaction time. In contrast, the research on driver risk taking has been conducted largely by questionnaires. Driver attitudes and personality are studied as indicators of the propensity to commit driving errors and traffic code violations, thereby raising accident liability. Thus, rather than focus exclusively on the driver's psychomotor or perceptual skills, attention is given to higher order cognitive processes and motivation (cf Rothengatter and Vaya, 1997). However, there is an issue of whether social desirability affects what is self-reported about driving behavior and self-reported about accidents (Wahlberg et al., 2010).

Self-reported violations and risky driving behavior, as assessed by driver behavior questionnaire measures, have been found to predict involvement in accidents, independent of the amount of yearly driving. Because self-evaluations of driving habits are longitudinally predictive of driving violations and accidents, it then becomes feasible to identify problematic drivers and augment their safety motives. Since these relationships hold strongly for young men, they are commonly a target group for intervention.

The most consistent finding about driver risk taking is its association with a sensation-seeking personality, which is thought to have a biological basis. High sensation seekers are more likely to drive drunk, exceed speed limits, take risks in passing and lane changing, not use seat belts, receive citations for traffic violations, and have crashes. These findings have been obtained in studies conducted in several European countries, Canada, the United States, Australia, and New Zealand. There is substantial research literature on the psychosocial factors influencing the risky driving propensity among young drivers, including speeding, drink driving, not wearing a seat belt, and driving while fatigued, as well as proclivity toward distraction.

Human behavior is high adaptive, and drivers adjust to changes in the intrinsic safety of the driving environment. In hazardous weather, drivers slow down and sharpen alertness. Alternatively, as safety in the driving environment is enhanced through improvements in roadway conditions and vehicle design, drivers may be inclined to drive faster, shorten the distance in following, overtake more readily, or be less attentive to hazards. Therefore, improved vehicle safety features may lead some drivers to overcompensate for perceived risk reduction, driving less safely because they feel more insulated from collision or injury.

Aggressive driving and its alias 'road rage' are prominent topics in the traffic safety field in many countries (Brewer, 2000; Galovski and Blanchard, 2004; Shinar, 1998). Aggression has been part of driving since chariots careened around the Circus Maximus in ancient Rome. Indeed, the symbolization of the automobile has been infused with themes of aggression, which is evident in vehicle names and designs. Uncontrolled anger and aggression on roadways do, of course, constitute a significant driver behavior issue, but neither the magnitude of the problem nor its societal trend is clear. While human aggression springs from many causes, aggression on roadways is a product of various disinhibitory influences (Novaco, 1991), such as anonymity, opportunity to escape, increasingly fortified vehicles, and strong elevations in physiological arousal produced by driving situations. The personalized territoriality of the vehicle and diffusion of roadway aggression scripts in the media also facilitate antagonism in driving when the behavior of other drivers is viewed as provoking.

Driver Selection, Training, and Rehabilitation

Psychologists have developed aptitude tests to insure public safety on road, rail, and air travel. Driving safety has been classically viewed as involving the three 'Es': engineering, enforcement, and education. Accident liability is primarily due to underestimation of risks, negligence or carelessness, personality, attitudinal disposition, or substance misuse, rather than to roadway or vehicle engineering. Hence, reduction in risky driving hinges on detection of problematic drivers and on driver training and rehabilitation programs. There is wide variability across countries in how systematically this is approached.

Reconviction for traffic offenses and for serious traffic offenses has been found in New Zealand national data, gathered prospectively, to be a function of age at first conviction, being male, number of prior convictions, and having a traffic conviction as the most serious offense; moreover, statistical models have achieved high predictive power in identifying traffic offenders at high risk for reconviction for an alcohol-related driving offense. In Germany, psychologists developed models to predict reoffending drivers, and their rehabilitation courses reduced drunk-driving recidivism. Specifically targeted driver education programs have been successful, but it has generally been found that secondary school driver training programs do not reduce accidents, as young people learn to drive from relatives and friends, not just schools. The propensity for risky driving, however, may be ascendant in a willingness to commit violations that can be detected in youth as predrivers (Rowe et al., 2013).

Older driver safety is a significant public health issue that is growing in magnitude (Wang and Carr, 2004). The number of people above the age of 70 who drive is progressively increasing, and that segment of the population is at greater risk for motor vehicle accidents due to cognitive and psychomotor functional impairments, the use of pharmaceuticals, and medical conditions. They are also more likely to die in a crash. Older drivers typically self-regulate by modifying their driving patterns (e.g., not driving at night; not using left-turn lanes). Advances in technology, including GPS navigation, collision avoidance systems, improved headlamps, and improved insulation from exterior noise serve to attenuate accident risk, but psychologists will continue to have important roles in developing driver screening systems and driver rehabilitation programs. How older drivers construe the risk of their driving (Siren and Kjaer, 2011) is an important psychological issue that bears on enhancing their safety and that of others.

Travel Demand and Alternative Modes of Travel

Transport systems planners use mathematical theories about choice in modeling travel demand, and psychological variables add to what is otherwise offered by economic models. Because choices are often grounded in perceptions and subjective valuations, psychological research methods help to ascertain the relationship between travel time and the desirability of travel mode options or goodness of fit with personal needs. Travel time, cost of alternative modes, availability of mass transit, activity plans, work demands, and personal preferences are weighed by the traveler in making transportation choices.

Psychological theory has been applied to change travel behavior, such as using reinforcement theory to boost transit ridership. Transit use has been promoted by offering cash and travel prizes through lottery-type drawings, as well as value coupons and tokens (for food, goods, and services) being distributed with bulk purchases of transit passes or dispensed contingent on boarding a bus. Similarly, inducements for ridesharing have been given by providing special lanes on congested freeways for multiple occupancy vehicles. Such schemes are more effective when the special lane has been added to the road, as opposed to when an existing lane has been converted. Other efforts to reduce solo driving have involved the provision of priority parking facilities and/or reduced parking rates for carpools and vanpools. Despite many schemes to boost carpooling and transit use, the 'drive-alone' mode share in the United States increased each decade from 1980 to 2010 (Pisarski and Polzin, 2013), which is unlikely to reverse as auto manufacturers continue to enhance private vehicle comfort and amenities.

Embedded in the issue of transit use is its social image, particularly with regard to buses. In many countries, persons of high social status commonly do intercity travel by rail for work commutes and discretionary trips, but bus travel typically has the image of being less than prestigious. As well, people may be disinclined to use the bus because of a desire to avoid crime victimization on the bus and at bus stops. Psychological knowledge can be utilized in modifying unfavorable images of transit use and to reduce unwarranted fears about safety risk.

Commuting Stress

Exposure to traffic congestion is stressful by virtue of impedance – the blocking or thwarting of movement and goal attainment. Travel impedance has both physical and perceptual dimensions (Novaco et al., 1990). 'Physical impedance' can be objectively measured by the distance and time of the journey, along with the number of road exchanges – each representing a node of congestion. Time of day is relevant, as congestion is greater in the evening, and commuting stress is compounded by strains from the workday. 'Subjective impedance' is the person's perception of commuting constraints, assessed by questionnaire items or structured interview. Because the commute is sandwiched between the home and the job, the demands and affordances of each of these domains, as well as personality factors, bear on the commuting experience.

Commuting stress has been found to be associated with elevated blood pressure, negative mood on arrival at work, negative mood at home in the evening, lowered frustration tolerance, cognitive performance impairments, illness occasions, work absences, job instability, lowered residential satisfaction, and decrements in overall life satisfaction (for reviews, Koslowsky et al., 1995; Novaco and Gonzalez, 2009). Female solo drivers in high-impedance commutes are most negatively affected, independent of job involvement and household income. Because women tend to have more logistical responsibilities for home and family, they are perhaps more sensitized to stress on high-impedance routes (Novaco et al., 1991).

A useful concept in understanding commuting stress is 'inter-domain transfer effects,' whereby the psychological consequences of environmental conditions in one life domain (home, commuting, work, or recreation) transfer to another, either positively or negatively (Novaco et al., 1990, 1991). An example of a positive transfer effect is that a high level of residential choice buffers commuting stress. Examples of negative transfer effects are that exposure to commuting stress affects negative mood at home in the evening (controlling for a great many other relevant variables) and that commuting stress prospectively leads to job location change, independent of job satisfaction. Automobile commuters have higher stress than train commuters having the same potential commute, and effort and unpredictability seem to be key mediating factors (Wener and Evans, 2011).

Dissatisfaction with the commute is a cost the employee absorbs, often with delayed effects on health and family life, but commuting stress also affects work organizations. People will change jobs to cope with traffic congestion, and commuting stress is more often manifested in illness-related absences from work and with impaired work performance. Working from home has possibilities for stress reduction, but telework has the tradeoff of constraining the restorative effects of being at home (Hartig et al., 2007).

Important Future Topics for Transportation Psychology

Transportation mobility restrictions present important psychological issues for a number of special populations, such as single working mothers with children, people who are physically or developmentally disabled, young drivers, and the elderly. Perhaps the most important problem area will be the needs and functioning of older adults, because of the growth in that sector of the population. In the United States in 1900, people aged 65 and more accounted for 4% of the population. By 2010, this percentage had grown to 13.0%, and it is estimated by the US Census Bureau that by 2030 it will be 19.3%.

Transportation problems for the elderly are exacerbated by suburbanization and by the vast majority of older adults being accustomed to driving automobiles. Decrements in visual, auditory, cognitive, and psychomotor skills that progressively occur with aging present societal challenges for scrutinizing the driving proficiency of older adults – for whom the loss of the driving license constitutes a major stressful life event. Without transit alternatives, older people become a transportation-deprived group. Many older adults progressively adjust to the decline in driving skills by ceasing to drive at night or avoiding turns across oncoming traffic; but such adaptations do not suffice for long, leaving many elderly unable to be licensed to drive. Physicians must remain aware of older driver safety issues in their clinical practice.

Projected technologies, such as automated roadways, are expected to ease transportation difficulties for the general population, but if automotive vehicles become significantly more cognitively complex to operate, this may be disadvantageous to the elderly. It can be expected that there will be substantial societal pressure to develop innovations in transportation to meet the needs of older adults who cannot drive and who do not have access to normal transit services. Wang and Carr (2004) called for efforts to optimize the driver, the driving environment, and the vehicle. The development of flexible and perhaps individualized transportation services for the elderly to facilitate grocery shopping, receiving health care, and going to religious, recreation, and cultural events is an important societal agenda that beckons for psychological input.

Advances in telecommunications will continue to affect commuting mode choice, and intelligent transportation systems (including roadway incident management) will affect travel times and travel safety. Governments will strive to get maximum capacity out of existing systems, but associated with government-instituted practices that flow from that motivation are personal privacy considerations. Surveillance, vehicle monitoring, event data recording, and vehicle control infringe on personal freedom, and psychological issues abound in that regard, including legislative matters.

Adaptation: An Over-Arching Concept

A core concept in the psychology of transportation is behavioral adaptation. Drivers and transport users will adjust to conditions in the transportation environment whether that be in roadway or transit conditions, their commuting scheme, their vehicle attributes, or changes in their skill level or state of functioning. People make adaptations to enhance their well-being, but some adaptations go awry, such as when enhanced vehicle design induces one to underestimate collision risk or use of nomadic devices while driving promotes multitasking

that makes for driver distraction. Adaptation occurs at different levels of analysis, ranging from 'high-level' trip and travel mode decisions to 'low-level' vehicle control behaviors that maintain safety margins. When the behavioral adjustments involved in adaptation are unsuccessful in the long term, more substantial behavioral coping can be expected, as when someone changes jobs to reduce commuting strain or stops driving because of age-related driving skill decrements. Innovations in information technology, by decreasing need for vehicle trips, progressively may facilitate positive adaptations to travel constraints imposed by congested roadways and to unwanted reductions in mobility for some populations.

Abstract

Transportation facilities are prone to congestion because of peaks in travel demand, inflexibility of supply, and inability to store transport services. Urban road traffic congestion and congestion in air travel impose significant economic and social costs. Traditional policies to alleviate congestion such as building new roads have had limited success at best. Congestion pricing has the greatest theoretical potential because it can affect all dimensions of travel behavior. However, congestion pricing of roads and airport runway slots has been resisted by policy makers.

Introduction

Technological advances in transportation since the industrial revolution have spurred the growth and spread of cities, enabled people to live far from where they work, and made long-distance business and recreational travel commonplace. Yet growth in travel has been accompanied by increasing adverse side effects: noise, air pollution, accidents, and – most importantly – congestion: the subject of this article. Congestion is certainly not a recent phenomenon. Two thousand years ago chariot riding was banned in Rome during peak hours because of traffic jams (Gibbs, 1997). But the automobile and other motorized forms of transportation have increased the prevalence of congestion in surface travel, and congestion in air travel has become a serious problem.

The most widespread and costly form of congestion is travel delay. Delay on the roads is manifest as reduced speeds, and queues at intersections and entrances to freeways. Air travelers suffer delay in checking in, passing through security, boarding an aircraft, waiting to take off and land, clearing customs and immigration, and retrieving baggage at the destination. These examples feature delay systems in which users experience delays but eventually complete their trips. Delay systems differ from loss systems, which have a finite capacity to accommodate users and reject further demand once their capacity is reached so that service becomes unavailable. For example, a flight cannot be booked if all seats have been reserved. A given transportation facility can sometimes be a delay system and sometimes a loss system. A bus is a delay system when it stops for passengers and waits for them to board and alight, and a loss system at full occupancy. And an airport is a delay system if arriving aircraft have to queue prior to landing, and a loss system if aircraft get diverted to another airport.

Crowding is a third form of congestion that is commonly experienced on buses, subways, and waiting platforms, in using luggage compartments on trains and aircraft, etc. Delay, unavailability of service, and crowding are problems not only in transportation but also in facilities associated with travel including hotels, restaurants, sports stadiums, recreational areas, and telecommunications. These facilities will, however, not be treated explicitly here.

Why Does Congestion Occur?

Transportation facilities are prone to congestion because of three characteristics of travel demand and supply: demand varies over time, supply is relatively fixed over long time periods, and output is not storable.

Temporal Variation in Demand: Travel demand has pronounced temporal fluctuations. Systematic daily and weekly variations are driven by work and school schedules, and by the operating hours of businesses, shops, and entertainment establishments. Seasonal variations in travel are induced by the timing and length of school holidays and religious festivals, by sporting event schedules, and by the seasonal nature of outdoor recreational activities. Travel demand also fluctuates irregularly due to sporting meets, fairs, and other "special events."

Rigidity of Transportation Supply: Transportation supply consists of infrastructure and vehicles. Infrastructure is generally long-lived and very costly and time-consuming to alter. Vehicles come in smaller and cheaper units than infrastructure, and have shorter lifetimes, but still last much longer than the time scale of demand fluctuations. Differences between regions and traveler groups in the timing of peak demands provide some scope to adjust supply by redeploying vehicles between markets although this is limited by constraints on the mobility of vehicles themselves (little or none for subways and trams).

Output Is Not Storable: A traveler or freight shipment must be present to be transported. Thus, like other services such as haircuts and concerts, but unlike commodities such as grain and steel, production cannot be stored to smooth imbalances between supply and demand.

As a consequence of demand fluctuations, rigid supply, and the impossibility of storage, the utilization rate of transportation facilities varies over time. Capacity is also variable due to accidents, strikes, bad weather, and so on. Because land is scarce and capacity is expensive, it would be prohibitively expensive to build enough capacity to prevent congestion at all times and in all circumstances.

Congestion is exacerbated by two further considerations. First, travelers usually lack incentive to account for the congestion costs they impose on other users. Usage fees are not charged on most roads, and the costs of registration, licensing, and insurance do not vary with distance traveled – let alone traffic

volumes. Access fees are levied at facilities such as waterways and airports, but the fees are usually either fixed or vary with usage crudely at best. Thus, congestion is a negative externality because its adverse side effects are not priced in markets. Second, transportation supply tends to lag growth in population and travel. Air travel volume in passenger-kilometers grew at an average annual rate of 5.7% from 1975 to 2005 (ICAO, 2007). Freight traffic measured in ton-kilometers grew at a rate of 6.9% over the same period. These high growth rates were spurred by airline deregulation in the United States in the late 1970s and subsequently in Canada, Australia, New Zealand, and Europe. Airport planning authorities, meanwhile, failed to invest adequately in runway capacity and air traffic control, or to price usage of airports efficiently.

The Costs of Congestion

Congestion imposes a range of costs on travelers: increased fuel consumption and vehicle wear and tear; extra travel time; the inconvenience of using an alternative travel mode or rescheduling, combining, or canceling trips; disutility from crowding; planning and psychological costs arising from uncertainty about arrival times; and (in the longer run) the costs of relocating jobs and residences. Delays are also costly for freight shippers. And unreliable deliveries can upset just-in-time manufacturing and increase the need for inventories.

Because travel delays are a dominant component of the total cost of congestion it is important to measure accurately the cost of travel time – known as the value of time (VOT). For passenger transportation VOT depends on the mode of travel, trip purpose, time of day, household time pressures, and other individual and trip-specific factors. Small and Verhoef (2007: p. 53) conclude from an extensive literature survey that the VOT is typically between 20 and 90% of the before-tax wage rate with an average about 50%. Estimates of VOT for air travel are generally higher than for driving, in part because many air travelers are on business trips with tight schedules and in part because individuals with high VOT prefer to take fast modes of transport. For freight transportation by truck the VOT depends on many factors: the type of commodity being transported, characteristics of the vehicle such as size and fuel consumption, drivers' wage rates, the importance of punctual delivery, whether the vehicle is operated in-house or for-hire, and so on. Average VOTs for truck trips are much higher than for car trips, and higher still when account is taken of the value of reliability (that is, the cost of unexpected delay).

Various estimates of the economy-wide costs of congestion have been compiled. For traffic congestion in the United States in 2011, Schrank et al. (2012) report a value of $121 billion, which is roughly 0.5% of gross domestic product (GDP). This figure includes time delay for passenger vehicles (valued at $16.79 per person hour) and truck operations (valued at $88.81 per vehicle hour), and extra fuel consumption. Comparable, recent figures for Europe are unavailable. The European UNITE project (Nash et al., 2003) estimated the costs of traffic congestion in the UK, France, and Germany to be 1.5, 1.3, and 0.9 of GDP, respectively. Aggregate statistics on the cost of air traffic congestion are patchy. Morrison and Winston (2008) report estimates for the United States that flight delays in 2005 cost passengers $9.4 billion in lost time and airlines $5.9 billion in additional operating costs. Ball et al. (2010) obtain larger estimates for 2007 of $16.7 billion for passengers, $8.3 billion for airlines, $2.2 billion for people who avoid air travel due to delays, and indirect costs of $4 billion in reduced GDP.

For several reasons aggregate statistics such as these should be interpreted with caution. First, they usually include only the more readily measured costs of congestion. Second, valuing time delay with a single number for VOT ignores differences across travelers as well as possible dependency on trip duration and the severity of the congestion encountered. And third, because eliminating congestion is not a practical option, measuring the total costs of congestion under actual travel conditions is not indicative of what might be gained from policies aimed at congestion relief. (On this point, see also Section Ways to Alleviate Congestion.)

These caveats notwithstanding, it is instructive to compare the costs of congestion with the costs of other transportation externalities. Small and Verhoef (2007: Table 3.3, p. 98) report estimates for the United States. Congestion costs account for about 64% of the total external costs of car transport, followed by accidents (24%) and environmental costs (6%). Delucchi and McCubbin (2011) present a wide range of estimates for all major modes of transport. For roads they find that accidents may impose the highest costs, with congestion costs ranking second. For air transport noise costs are highest, followed by congestion. Friedrich and Quinet (2011) compare these estimates with estimates for Europe and conclude that they are similar in both magnitude and ranking. Overall, the costs of congestion thus appear to be appreciable both in absolute terms and relative to other externalities.

Modeling Congestion in Transportation Facilities

Transportation congestion modeling has been taken furthest for road traffic. Various approaches are described in Daganzo (1997), Small and Verhoef (2007), and Lindsey and Verhoef (2008). Modeling the behavior of individual drivers is a daunting task not only because of their sheer number but also because drivers – being self-interested, fallible, and heterogeneous – do not behave like atoms according to universal and immutable physical laws. Traffic microsimulation models have nevertheless been developed that can simulate the behavior of large numbers of individual vehicles within a predefined road network. These models are well-suited to simulating queuing conditions on urban roads, and analyzing signal timing and other traffic control measures as well as policies such as lane-narrowing. Useful insights into the economics of traffic congestion can nevertheless be obtained by using conventional supply–demand diagrams in which the time dependence of traffic flow is ignored and vehicles are treated as a homogeneous continuum.

Consider **Figure 1**, but ignore all its details for now – which will be covered later. The average cost (AC) curve passing through points *F*, *G*, *J*, and *M* depicts the cost borne by each driver to take a particular trip as a function of the traffic volume; i.e., the number of vehicles that make the trip per hour. Average cost includes vehicle operating cost plus travel

Figure 1 Trip costs, equilibrium, and optimal usage in a delay system.

time, which is assumed to be valued equally by all drivers. At low volumes, vehicles are far enough apart that they can proceed under free-flow conditions, so that the trip cost curve is horizontal between *F* and *G*. At higher volumes, drivers are forced to slow down to maintain a safe following distance. Travel time rises and AC slopes upward. The shape of AC depends on road design, speed limits, vehicle size and handling characteristics, weather conditions, and driver reaction times and preferences for risk-taking. Due to changes in these factors over time, driving speeds have increased and following distances have decreased, thereby boosting effective road capacity and shifting the AC curve down.

The marginal social cost (MSC) curve in **Figure 1**, passing through *F*, *G*, *H*, and *L*, is derived by adding to AC the cost of the congestion that each driver imposes on others. The MSC curve coincides with AC over the interval from *F* to *G*, and lies above AC elsewhere. To determine how many trips are taken, a demand curve can be added as shown by the downward-sloping curve passing through *A*, *H*, *M*, *S*, and *U*. In the absence of traffic control or other means of regulation, equilibrium is established at point *M* where the marginal willingness to pay for a trip as measured by the demand curve matches the cost, AC. The unregulated equilibrium number of trips is *OR*. By contrast, the socially optimal number of trips, *OK*, is found at point *H* where the demand curve intersects MSC. Fewer trips per hour are taken than in the unregulated equilibrium, although travel is still congested because trip cost, *JK*, exceeds free-flow cost, *OF*. One way to support the optimum is to impose a toll equal to *HJ*: the difference between MSC and AC with traffic volume at *OK*. This is the basis behind congestion pricing, to be discussed in Section Congestion Pricing.

At the unregulated equilibrium, the congestion cost imposed by each driver is *LM*. Some studies have estimated this quantity to be several times as big as *MR* during peak periods in large cities. To get a figure for aggregate congestion costs it is tempting simply to multiply *LM* by the number of trips, *OR*, to get area *LMDB*. But this is inappropriate since the number of excessive trips taken in equilibrium relative to the social optimum is only *KR*. Similarly, it does not make sense to evaluate the congestion cost at the optimum, *HJ*, and multiply it by *OK* to get area *HJEC*.

A more practically useful measure of congestion costs is the difference between the net social benefits of travel at the optimum (area *AHJE*) and at the unregulated equilibrium (area *AMD*). This difference can be decomposed into the reduction in costs on the *OK* trips that continue to be taken at the optimum (diagonally shaded area *IJED*) minus the loss of benefits on the *KR* trips that are no longer taken (vertically shaded area *HMI*). The difference in net social benefits can also be determined by computing the net social cost of the *KR* excessive trips taken in equilibrium. This quantity is equal to area *HLM*, which must therefore equal *IJED-HMI*.

Note that the cost of travel under free-flow conditions plays no role in the calculations. One could of course calculate the difference in cost between equilibrium and free-flow conditions, *MQ*, and multiply it by *OR* to get area *MQFD*. But this would be relevant only if it were somehow possible to maintain free-flow conditions at any traffic volume. Traffic volume would then increase from *OR* to *OV*, and a better measure of the gains would be the increase in net social benefits: area *MUFD*.

Supply–demand diagrams such as **Figure 1** are applicable not only to automobile traffic but also to other delay systems such as airport runways, bus service, waterways, and pedestrian walkways. In the case of loss systems, the AC curve is approximately horizontal up to capacity flows and it is therefore optimal to use the facility to capacity while avoiding queuing or other wasteful forms of rationing access. In practice, demand cannot be predicted perfectly and a (probabilistic) tradeoff exists between unused capacity and congestion. Airlines deal with this tradeoff by using sophisticated yield management software that set fares according to the average fraction of seats that are occupied on a given flight.

Though useful, the simple supply–demand approach does abstract from various real-world features of transportation

congestion. First, roads, airports, and other facilities are components of transportation networks. Costs at one facility can depend on usage at other facilities because of conflicts between traffic flows, spillovers of queues, and so on. Such interactions may cause throughput to decline with traffic density and even deteriorate to a state of gridlock. Second, users differ in the congestion they create. Traffic engineers make allowance for differences between road vehicles in size, speed, and maneuverability by using passenger car equivalents that depend on grade and other road characteristics. And third, the static supply–demand approach ignores fluctuations in travel demand over time and does not address trip timing decisions. Vickrey (1969) developed a tractable model of trip-timing decisions which is now widely used. His and other dynamic congestion models are reviewed in de Palma and Fosgerau (2011).

Ways to Alleviate Congestion

Many policies have been adopted to relieve congestion. Some – such as land-use controls – have additional objectives, whereas policies such as road pricing are targeted at congestion. Discussion will be limited here to three policy instruments: capacity investment, congestion pricing, and information technology.

Investment

The traditional approach to congestion relief is to expand capacity. Investment shifts the AC curve in **Figure 1** down, as shown by the dashed line passing through points *P* and *S*. A new unregulated equilibrium is established at *S*. Two benefits result: a reduction in travel costs for the *OR* preexisting trips, and the benefit to travelers from the *RT* new trips which can arise from changes in mode, route, departure time, and other choices. But because the new trips contribute to congestion, travel costs decline by only *MN* rather than by *MP*, and this partly undoes the cost savings to previous users. The generation of new trips is a manifestation of so-called latent (hidden) demand that was not apparent prior to the investment (Duranton and Turner, 2011). The strength of latent demand depends on the geographical scale of the capacity investment, the time period considered, the quality of public transit alternatives, and other factors. Though the increase in usage can be appreciable if the demand curve is relatively flat, latent demand has frequently been overlooked in engineering and cost–benefit studies of investment. Even worse than latent demand, capacity expansion on one link of a transport network can induce shifts of demand to more congestion-prone routes or travel modes that actually raise overall travel costs (Arnott and Small, 1994).

Unlike the unregulated equilibrium, investment always yields a positive gross benefit for the social optimum. The effects can be assessed by tracing the rightward shift of the MSC curve (not shown in **Figure 1**). Depending on the strength of latent demand, the benefits may be greater or smaller than for the unregulated equilibrium. More generally, the benefits of investment, and hence optimal capacity too, depend on how traffic is regulated and priced.

Congestion Pricing

Congestion pricing has been promoted by economists since the 1950s. It makes use of the price mechanism, with all its advantages of decentralized decision-making. And, unlike other policies, congestion pricing restrains latent demand and generates revenue that can be used to fund infrastructure investment and maintenance. The biggest potential gains from congestion pricing in transportation appear to be for road traffic and airport runways.

Road Pricing

Road pricing technology has come a long way since drivers were obliged to stop and pay cash at toll booths (de Palma and Lindsey, 2011). Thanks to advances in automatic vehicle identification and electronic toll collection, tolls can be levied anonymously using prepaid smartcards while vehicles maintain highway speeds. Several European countries now use satellite technology for tolling trucks on intercity motorways. The biggest virtue of road pricing is that it can influence all dimensions of travelers' choice. It is also consistent with the user pay principle.

The optimal toll in the static supply–demand framework of **Figure 1** is *HJ*. The imposition of this toll raises travel cost by *HI* relative to the no-toll unregulated equilibrium. That road pricing tends to make drivers worse off is one of the reasons for longstanding opposition to it. Another is that road pricing is often seen as 'just another tax.' There is growing recognition that to generate political support for road pricing, toll revenues must be used to benefit travelers without undoing incentives for them to curb their travel. Possibilities include improving public transit, reducing gasoline taxes, and investing in roads themselves. New self-financed private toll roads are showing promise as a market-oriented approach to alleviating congestion (Small, 2010).

The simple supply–demand approach of course abstracts from various real-world complications in the implementation of congestion pricing, including setting tolls on a network, varying tolls over time, charging for parking, and avoiding harm to lower income drivers. These obstacles are largely responsible for the slow implementation of congestion pricing. The main successes are electronic road pricing in Singapore, the London congestion charge, the Stockholm cordon charge, and high occupancy toll (HOT) lanes in the United States. None of these schemes adheres rigorously to theoretical prescriptions for congestion pricing. Nevertheless, all except London employ time-varying tolls, and on some HOT lane facilities tolls are adjusted every few minutes to maintain high speeds on the toll lanes. Road pricing practice is reviewed in Small and Verhoef (2007: Section 4.3), Parry (2009), and Santos and Verhoef (2011).

Pricing Airport Runways

Traditional means of allocating runway space are a far cry from congestion pricing. Access to runways has been determined by scheduling committees that may be dominated by representatives of major airlines operating at the airport. And landing fees have been based on aircraft weight, which reflects congestion cost only crudely. Congestion pricing of runways would be administratively easier to implement than road pricing because

takeoff and landings are recorded at airports anyway, and since the transactions costs for a flight are spread over many travelers.

The virtues of congestion pricing of runways were recognized in the late 1960s. Pricing encourages airlines to schedule flights off peak, to use lower cost airports, and to deploy larger aircraft which create less delay per passenger. One complication is that some airlines operate a large fraction of the flights at an airport and have an incentive to internalize the congestion costs their flights impose on each other. Brueckner (2002) shows that the theoretically optimal congestion charge varies inversely with an airline's market power so that optimal tolling would be discriminatory with large carriers charged less than small ones. A number of theoretical and empirical studies have assessed the practical significance of this 'self-internalization' hypothesis with no consensus yet reached. Morrison and Winston (2007) estimate that optimal discriminatory tolling at US commercial airports would yield an annual benefit of $2.7 billion. Nondiscriminatory charges yield only slightly lower benefits of $2.5 billion which suggests that discrimination might not be worthwhile given the higher administration costs and likely political opposition. An alternative to charging for every use of runways is to auction tradable take-off and landing slots. Slot trading was introduced in 1986 at Washington National, Chicago O'Hare, and New York's La Guardia and Kennedy airports, and has worked well. Airport congestion pricing and slot trading are described in Zhang and Czerny (2012).

Information Technology

Development of Intelligent Transportation Systems (ITS) technology began in the 1970s. These systems are now widely used to monitor traffic and to respond quickly to accidents by dispatching emergency services. ITS technology in the form of Advanced Traveler Information Systems is also used to inform travelers about travel conditions. Information is made available by traditional sources such as television, radio, and changeable message signs, as well as via traffic web sites, and it is accessible using cellular phones, smart phones, other handheld devices, and in-vehicle computers and global positioning systems receivers. Travelers can receive traffic alerts by short message service, automated voice call, and e-mail. They can use the information to adjust their travel mode, departure time, route, and other decisions, and they can use it as a navigational aid for way-finding and locating services.

Most studies conclude that ITS technology helps to alleviate traffic congestion and reduce accidents, pollution and carbon-dioxide emissions. Still, the potential of ITS is limited by the fact that drivers can disregard advice if they believe it is not in their self interest. And, similar to the effects of capacity expansion, better information can induce people to travel more because it reduces the costs of travel. This shortcoming can in principle be overcome by implementing road pricing in tandem with ITS.

General Policy Conclusions

From a theoretical perspective congestion pricing is the most effective means of controlling congestion because it influences all travel choices and also contains latent demand. But for various reasons – including the cost of pricing all links on travel networks, equity concerns, and the need to maintain safety – nonprice constraints on travel such as air traffic control and regulations on the movement of heavy road vehicles will persist.

Looking Ahead

Despite the hazards of forecasting it is tempting to speculate about how congestion in transportation will evolve in the years to come. Vehicle ownership and usage is likely to continue growing in China and other developing countries for many years, and cities such as Beijing, Shanghai, and Bangkok are now among the most congested in the world. Until 2006, aggregate congestion indexes suggested that traffic congestion was also getting worse in the United States (Schrank et al., 2012). But congestion has since eased in the United States and most other major developed countries. Evidence is growing that personal traveled has reached a plateau and even started to decline (Millard-Ball and Schipper, 2011). Among the possible reasons are economic stagnation, rising fuel prices, aging of the population, continuing urbanization, and mounting health and environmental concerns. Young adults are postponing purchase of vehicles as well as homes that encourage use of personal vehicles. People can adapt to congestion by adjusting departure times, destinations, residential location, and other choices. Congestion costs are also held in check by the trend toward flexible work times, late night, and weekend shopping, and extended hours of other services. And, most fundamentally, the costs of congestion are borne largely by travelers themselves. Congestion is a self-limiting phenomenon in the sense that the private cost of travel can never exceed the private benefit derived from it.

The effects of current and possible future technological developments on congestion are ambiguous. Innovations such as air conditioning, car stereo systems, books on tape, and traveler information systems mentioned above have made driving more pleasant and allow people to make productive use of time in the car. Similarly, laptops, cellular phones, and executive lounges at airports make delays in air travel less onerous. By reducing the costs of travel these developments might be expected to encourage travel and increase congestion delays.

Technologies such as telecommuting, teleconferencing, teleshopping, Fax, electronic mail, the Internet, and other telecommunications devices offer alternatives to personal and business travel as well as postal mail and courier services. But telecommunications also complement travel by helping people establish new contacts, and learn about new products and places to visit (Mokhtarian, 2002).

And the option of telecommuting may encourage people to live in more remote locations, so that when they do commute they have further to go. Part of the time freed up from commuting may be used to make other trips, and any reductions in travel by telecommuters may be partially offset by latent demand from the rest of the population.

Rapid advances are being made in vehicle design. Electric vehicles promise to deliver major environmental benefits, but their effects on traffic congestion are likely to be more modest.

In the longer term, automated highways, self-driving vehicles, and vehicle-to-vehicle communications could provide huge benefits in congestion relief, fuel savings, and safety. They may also reduce the amount of space required for roads and parking (The Economist, 2012). Nevertheless, these technologies will take many years to phase in, and they pose major technological and legal challenges. In the meantime, the battle against traffic snarls as well as airport delays and congestion on other transport modes will continue to be waged on several fronts.

Trials

Abstract

This article identifies distinctive features of various forms of trial in different legal systems, and then explores the social functions and the operational details of trials in Western societies. In doing so, it raises perhaps the most persistent question social scientists ask about trials: Which is the best form for resolving disputes?

Introduction

It is tempting to adopt the definition of trials offered by Lon Fuller, the leading authority on the concept adjudication, who defines the trial as a process, which permits disputants "an opportunity for the presentation of proofs and reasoned arguments" in order to give "formal and institutional expression to the influence of reasoned argument in human affairs." As such, trials "assume a burden of rationality not borne by any other form of social ordering" (Fuller, 1981, pp. 93–94). Although this description probably captures cultural assumptions about the contemporary Western trial, it fails to encompass the idea of a trial more generally. It treats human rationality as a given rather than a variable, and it assumes that the primary focus of trials is to resolve disputes, rather than to clarify policy or to assert authority.

I suggest an alternative: a trial is a process by which proof is authoritatively established. Rationality can be but is not necessarily involved in the process, parties affected may or may not have an opportunity to offer proofs or to make reasoned arguments, and there may or may not be a 'dispute.' This more general definition is useful in accounting for a greater variety of processes that are generally understood to be trials, although in widely different settings, including so-called simple or primitive societies, intensely religious societies, and modern Western societies. It also includes processes in which there are no 'disputes,' and where disputes are not 'resolved' so much as they are processed (*see* Courts and Adjudication).

A good place to start in thinking about this more generic definition of trial is Max Weber's analysis of rational and irrational forms of legal decision-making (Weber, 1954; Trubek, 1972). For Weber, forms of legal decision-making vary along two dimensions: the nature of their rationality and their degree of formality. By rationality, Weber meant the presence or absence of 'general rules' that are to be invoked in decision-making. A rational legal system (and decision), according to Weber, involves use of abstract, calculable, and general principles that are invoked when deciding a particular case. In contrast, an 'irrational' system does not rely on the application of general rules to particular facts or cases, but is guided by a holistic process that may not be determinable in advance of the particular decision. Similarly, Weber pointed out, legal decision-making varies in its degree of formality. At one end of the continuum is a formal legal system that is autonomous; it has a distinct set of 'legal' norms and procedures to guide legal decision-making, and perhaps also a distinct set of offices and officials to make decisions. At the other end of the continuum are not casual, informal norms but rather an array of substantive norms, a mixture of legal, religious, moral, and practical precepts that are intermixed and undifferentiated, and so do not constitute a separate and distinct set of (formal) legal norms. In this way, Weber distinguished formal justice from substantive justice. In proceedings dispensing substantive justice, religious, traditional, societal, ethnic, and family norms may blend with distinctively legal norms; here, strictly legal decision-making and decision-makers are not always distinguishable from other realms of social behavior and social actors (*see* Weber, Max (1864–1920)).

Legal decision-making can vary independently along both dimensions, so Weber developed a set of ideal types that has often been used to characterize distinct forms of legal decision-making across time and across cultures. They are presented in Table 1.

Table 1 generates four identifiable types of 'trials': (1) informal irrational (substantive irrationality), (2) informal rational (substantive rationality), (3) formal irrational, and (4) formal rational. The two extremes on the diagonal (cells 1 and 4) are familiar to many students of law and the social sciences. Readers of Weber are familiar with the example for cell 1 – the idea of decision by a *khadi* (an Islamic clerical judge), who after hearing a case hands down a ruling without explicit reference to any general rules. Weber believed that the outcome is understood in Islamic culture and elsewhere as an expression of divine inspiration transmitted through the *khadi*, and that the ruling applies only to the particular case in hand. By contrast, cell 4 represents the trial in the modern, rule-of-law

Table 1 Weberian typology of legal decision-making

Degree of formality	*Degree of rationality (presence or absence of general rules)*	
	Irrational	*Rational*
	I	II
Informality (substantive justice)	Substantive irrationality Khadi justice	Substantive rationality Cost–benefit analysis
	III	IV
Formality (formal justice)	Formal irrationality Trial by ordeal	Formal rationality modern Western trial

Adapted from Inverarity, J., Lauderdale, P., Feld, B., 1983. Law and Society: Sociological Perspectives on Criminal Law. Little Brown, Boston.

state of the sort Fuller (1981) had in mind. Facts are introduced and testimony is taken according to a clear and precise set of procedures, and this evidence is judged in light of predetermined rules. It is this type of decision-making that Fuller had in mind in his discussion of the forms and limits of adjudication. Turning to Weber's two other types of decision-making, cell 2 represents substantive rationality, a form of decision-making that does not entail a distinct and separate legal sphere but melds law with norms in other social realms (or, more precisely, separate realms are not differentiated). Examples include legal decisions based upon cost–benefit analysis or religious precepts. Such decisions are 'substantive' not 'formal,' since they do not derive legitimacy from a distinct and separate legal sphere. Yet they are 'rational' in that they specify clear norms, rules, and procedures. Cell 3 describes a process that is formal in that it depends upon specialized and distinct legal procedures. But because decisions flow from an ineffable process rather than from general rules, the process is irrational. A familiar example is the establishment of proof through appeals to divine intervention – ordeal by fire, ordeal by water, or other attempts to invoke supernatural signs. Whatever its defects, this last set of procedures for establishing proof had one virtue, if only for true believers: certainty of outcome (*see* Law and Development).

The discussion above suggests that what Fuller had in mind as the essence of the trial is in fact only one of several forms of legal decision-making. However, he is not so far from the mark. Weber's purpose in developing the typology outlined above was not only to emphasize structural variability in legal decision-making, but also to set the stage for his theory that modernization requires the adoption of formal legal rationality. He saw formal rational adjudication, like bureaucratization, as one of the essential features and defining characteristics of modernity. It is therefore important to understand what is lost by abandoning the other three forms of decision-making in his typology, and what is gained by adoption of the fourth form. According to Weber, modern law undermines competing forms of authority. To the extent that modern law triumphs – and law is notoriously good at triumphing – legal precedent, legal decision-making, and hence the modern trial overshadow tradition, custom, the family, and religion as sources of authority. In this sense it simplifies and rationalizes autonomous legal authority. The modern idea of the rule of law also aspires to precision; it identifies legal entities and separates them from other forms of control. Thus, it offers both a sense of freedom and predictability at the same time. In a modern system the ruling at a trial trumps other commitments, relationships, and rule systems. That is, the modern trial privileges the state: as officials of the state, modern judges are part of the state-made legal system, and must apply only state-made law. Modern trials undermine other legal systems and challenge the idea of legal pluralism. However, there is a continuing debate about how autonomous modern law is or must be (Nonet and Selznick, 1978).

The Multiple Functions of the Trial

Privileging state law and trials, as formal rational forms of decision-making do, does not mean that there are no differences in the nature and function of trials in modern states. Forms and functions of trials vary widely in modern societies. Damaska (1986) argues that states with traditions of strong government rely on trials not only as means to handle disputes between the parties, but also as opportunities to reassert and to implement state policies. In contrast, weak states tend to view trials in conflict-resolution terms. European countries with traditions of strong central government and civil law systems are examples of the former, while Great Britain and the United States, less-centralized states and common law systems, are examples of the latter. Predictably, settlements in lieu of trial are formally discouraged in the former set of countries and encouraged in the latter. This doubtless helps to explain why common law countries have a much higher proportion of cases commenced in courts are eventually settled short of trial, relative to most countries with civil law systems (Kritzer, 2004). Political scientist Martin Shapiro, who has explored some of the same themes developed by Damaska (Shapiro, 1981), maintains that always and everywhere, courts – including trial courts – in addition to being institutions for conflict resolution, are important agents of social control. He means that in all societies courts are used by the dominant political regime to help promote its agenda. Trials, therefore, always serve two simultaneous and symbiotic functions: they resolve conflicts among the immediate parties, and they provide an opportunity for a type of micromanagement, in the pursuit of regime interests. When trial courts strive to assert independence and do not or will not serve the latter function, Shapiro argues, their jurisdiction will be curtailed. For example in the mid-twentieth century, when English courts failed to rule in favor of labor unions frequently enough at trial, their jurisdiction was curtailed and special labor relations courts, more favorable to labor, were established.

In a more generalized analysis, Durkheim's ideas of social solidarity rest in part upon his understanding of the social functions served by the legal process, including trials (Durkheim, 1964). Although his writings focus on punishment and the criminal process, his overall theory emphasizes the solidifying function of a variety of legal institutions, including the trial. Much of the dramaturgy associated with the process of punishment is also found in the rituals of the trial. Trials, and public reactions to them, represent an important and visible expression and reassertion of Durkheim's 'conscience collective.' Labeling theorists in the social sciences have seized upon this symbolic function, and have explored its relevance for the criminal trial. In a classic article, Garfinkel described the criminal trial as possessing all the necessary 'conditions of a successful degradation ceremony' (Garfinkel, 1956). Similarly, Stuart Scheingold (1977) and others have argued that trials, and particularly high-profile trials, function to foster a 'myth of rights,' which serves to undermine disruptive political struggles. Symbolic victories at trial give the appearance – but not necessarily the reality – of change, and as a consequence they foster political quiescence (Scheingold, 1977). Others have explored the more overtly political functions of some trials (*see* Judicial Review; Political Trials; Political Lawyering).

Clearly one of the basic functions of trials is to resolve conflicts. Yet, some social scientists question even this seemingly obvious notion. Unlike mediation, where the parties

participate by mutual consent, a trial is a process in which at least one party is an unwilling participant. Consider, for example, the criminal defendant whose appearance must usually be coerced. Moreover, modern law does not necessarily express the deeply valued norms of any tightly knit community or even widely held norms. As a consequence, both the institutional framework and the norms applied may be regarded with suspicion, if not hostility, by one or more of the participants at trial (Shapiro, 1981). Various scholars of legal pluralism emphasize just how problematic these challenges are, and often criticize governments and other scholars for giving pride of place to the formal legal trial as the preferred institution for dealing with conflicts (*see* Legal Pluralism). In light of these and related concerns, it is conceivable that a verdict by a court may not always be an effective way to resolve conflicts, especially in the eyes of the losing party. Consequently, many people who lose at trial continue to press their claims in other forums (Abel, 1982, 1983). Others do not even bother to seek redress in courts (Felstiner et al., 1980–91) or seek out formal alternatives to adjudication (*see* Disputes, Social Construction and Transformation of; Law, Mobilization of).

Trial Complexity and Its Consequences

One distinctive feature of modern trials is the replacement of reliance on divine intervention with modern empirically based decision-making. Factual evidence subjected to scrutiny has replaced the evidentiary value of supernatural signs. Eyewitness testimony has superseded oath-taking by the accused. And gathering, sifting, and pondering evidence has been transformed from an informal process into a disciplined arrangement governed by detailed procedures and formal rules. Consider that the earliest-known juries convened in criminal cases in Anglo-Saxon England consisted of men from the local community who had firsthand knowledge about the case and/or the character of the accused. By the nineteenth century, a jury was a group legally barred from any firsthand knowledge of the facts of the case before it, and could receive only evidence screened by highly complex rules and introduced according to complicated procedures. In most ordinary cases, the medieval trial was a relatively informal and brief affair handled by the parties involved in the dispute. But the modern trial is dominated by lawyers – highly trained and paid professional advocates for the parties to the dispute – who must contend with the proliferating subtleties of modern substantive law, and who must practice according to increasingly complex rules of evidence and procedure.

Differences in the structure of the trial process produce a number of important differences in effects. In systems with jury trials, proceedings are likely to rely heavily on oral evidence. But in European and other legal systems that do not have or do not rely so heavily on juries, the trial often proceeds by written submissions to the court. The court confronts a dossier containing statements of facts and conclusions and sworn testimony (depositions), not a series of witnesses telling their stories in open court. Additionally, in systems with juries, the trial once begun is likely to run continuously until each side has rested its case. By contrast, a trial by dossier is likely to be intermittent and extend over a much longer period of time. These differences also affect the pace of true closure to the litigation. Cases in courts with active juries are almost always concluded within a few days of commencement, and verdicts are typically handed down very shortly thereafter. But in systems without juries, with trials by dossier, evidence-gathering is far more protracted, and final judgments are not necessarily issued shortly after submission of the final bit of evidence. Thus, ironically, although the jury-trial system is often criticized as inefficient, it may actually foster expeditious trial proceedings (*see* Juries).

The nature and form of different trial systems have other consequences as well. The conventional understanding is that Anglo-American legal systems have developed elaborate rules of evidence and procedure in order to restrict the power of jurors, who are untrained lay decision-makers. Since civil law systems have had no such need, they have simpler rules. Although these claims have been vigorously disputed, there is no doubt that rules of evidence and procedure in civil law systems with no juries or weak juries are far simpler than those in common law systems with predominant juries. The 'quest for perfect justice' invoked to justify the complexity of common law trial proceedings may be counterproductive (Pizzi, 1999). Trials are swifter, cheaper, and perhaps fairer in many civil law countries than they are in the United States and England. Feeley and Lester (1994) have traced increases in length and complexity of trials in England in the eighteenth and nineteenth centuries, and attribute the changes to the growing complexity of rules of evidence and procedure as well as the greater use of representation by lawyers. Examining the comparative effects of European and American trials in the late-twentieth century, Kagan (2001a,b) has shown that the expansion of 'adversarial legalism' in the United States dramatically increased the cost and length of trials without offering any corresponding increase in benefits (*see* Litigation; Legalization: The Expansion of Law's Domain).

This tendency to increase trial complexity and adversariness in the quest for judicial perfection led legal historian John Langbein to liken the modern adversarial criminal trial to Medieval European proceedings (Langbein, 1976, 1978). Both systems, he argued, aspired to 'perfect justice' but in fact precipitated disastrous results. Impossibly high standards of proof in medieval law led jurists to transform torture into a legal expediency in order to fulfill their need for certainty (which confession could provide). Contemporary jurists have developed a functional equivalent, the coercive practice of plea bargaining, to facilitate a similar objective (*see* Plea Bargaining: A Comparative Analysis). Certainty of outcome in both cases, Langbein argued, becomes a mere legal nicety, since both arrangements depend upon coercion. Both torture and plea bargaining are little more than loopholes to circumvent unrealistically high standards of proof. Simpler proceedings and more realistic expectations, Langbein and many others have maintained, would result in fairer and more workable trials (*see* Legal Formalism; Civil Law; Torture: Legal Perspectives).

Finally, in a very real sense the term 'trial' is misleading and is perhaps an outmoded concept. It implies a single coming together of the parties in a forum where facts are presented and issues resolved. Although a great many cases are handled in

a single session, most cases involve a series of hearings and/or decisions that may extend over a significant period of time. Consider a putatively 'simple' criminal case; a suspect is arrested and taken to court for an arraignment, at which time she/he is asked to enter a plea and bail is set. If pretrial release is not effected, there may be subsequent bail hearings. There may be separate hearings on such issues as a request for representation by a legal aid attorney, probable cause, a motion to suppress evidence, a motion to dismiss, or separate trials for codefendants; there may be a hearing to determine guilt, a sentencing hearing, and appeals on any of the issues just mentioned. Each one of these separate proceedings can be considered a trial in that it can result in an adjudicated determination of an issue. Contrast to this simple criminal case with complex civil cases, which can involve dozens of such issues and hearings. Under such conditions, it does not make much sense to talk about either a 'case' or a 'trial,' since contested issues have been authoritatively resolved at any number of different hearings; issues may have moved from trial courts to appellate courts and back several times, and indeed the name of the 'case' may have changed (Feeley and Rubin, 1998). European legal scholars are more likely to understand the term 'trial' in this elaborated sense than are Anglo-Americans, who are more familiar with the idea of concentrated, continuous oral proceedings. Yet, the ambiguity of the word is likely to persist in the context of most modern, complex systems of litigation. In light of this, it may be more useful to use the term 'dispute processing' (Abel, 1982, 1983).

Whither the Trial?

Trial rates in most industrialized countries have been declining steadily since the early nineteenth century, as negotiated settlements have replaced them. Judges often encourage such settlements, which they often see as rendering greater fairness and effectiveness than would be provided by a trial, and of course settlements are much more efficient (the judge may only have to formally acknowledge the outcome). But since the late-twentieth century, an increasing number of scholars and judges have noted the steady decline of the trial rate (Heyderband and Seron, 1982; Galanter, 2004), and suggested the low level is disturbing. Some argue it represents the triumph of administrative rationalization over justice (Heyderband and Seron, 1982), and others worry that it means that litigants are effectively barred from access to justice, and still others that few trials mean even fewer appeals, which can clarify law and establish precedents (Mulcahy, 2013). Certainly, the arc of the twentieth century saw a marked decline in trials in both civil law and common law countries, but it is difficult to know what to make of this trend. Simultaneously more parties have been represented by lawyers (Feeley and Lester, 1994) and by more and better lawyers, and during this same period the trial process has experienced elaboration. There are more pretrial motions to consider, such as motions to suppress, probable cause hearings, to grant discover, for summary judgment, and the like. Outcomes in such 'preliminary' matters can often be a fairly clear signal as to what the likely outcome of a case may be, and these adjudicated rulings serve as an encouragement to settle. Still, as trial rates approach to zero in the United States and other jurisdictions, and private systems of mediation and arbitration are imposed on parties through contract, the meaningfulness of the idea of one's day in court and a 'fair hearing' can be questioned (Merry and Silbey, 1984).

Triangulation: Methodology

Linda Heath, Loyola University Chicago, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

At its simplest level, triangulation refers to the use of multiple measures to capture a construct. The triangulation strategy, however, can be applied to multiple operationalizations of treatments and manipulations and to the use of multiple theories, analyses, analysts, methodologies, and research designs and approaches. The history, logic, extensions, limitations, and recent applications and developments of triangulation will be examined in this article.

Introduction

Triangulation has been called "a veritable 'magical' word in mixed methods research" (Tashakkori and Teddlie, 2003: p. 674) and a "near-talismanic method" to combine qualitative and quantitative research (Miles and Huberman, 1994: p. 266). On the other hand, triangulation has been said to be "over-used to the point where it means nothing" (Tashakkori and Teddlie, 2003: p. 674) and to "have too much meaning," therefore having "no meaning at all" (Sandelowski, 2003: p. 328). So what is this magical, near-talismanic, perhaps meaningless thing? At its simplest level, triangulation refers to the use of multiple measures to capture a construct. The triangulation strategy, however, also can be applied to multiple operationalizations of treatments and manipulations and to the use of multiple theories, analyses, analysts, methodologies, and research designs, to name but a few applications. The use of triangulation logic in the social sciences emerged at the time that the quantitative purist or positivist approach was challenged by a qualitative purist or constructivist approach (Johnson and Onwuegbuzie, 2004). At a basic level, the triangulation strategy requires an acknowledgment that no one measure in the social sciences is a perfect measurement of the construct under consideration. With only one measure of the construct, the error and biases inherent in the measure are inextricably confounded with the construct of interest. Although this triangulation logic initially was explicated in the social sciences in terms of measures and methods with Campbell and Fiske's (1959) development of the multitrait-multimethod design, the same logic can be extended to treatments, settings, populations, and many other aspects of the research enterprise, and, many research programs used triangulation logic before the term was first imported into the social sciences. Although simple in concept, triangulation "carries with it a host of implications regarding the proper conduct of social research, the effects of imperfection or unreliability of measurement operations on the development of theory, and the manner in which our field might gradually attain the status of the more developed sciences" (Crano, 1981: p. 320).

History of Triangulation Concept

More than 40 years ago, social scientists called for triangulation of research measures as a means of more adequately capturing the essence of the construct under consideration (Campbell and Fiske, 1959; Webb et al., 1966). The term 'triangulation' was probably borrowed from surveying, where multiple measures from different vantage points are used to locate an object in space by creating a triangle of three points when only two points can be measured directly. Although Erzberger and Kelle (2003) argued that "this notion loses much of its clarity when transferred to the realm of social science methodology (because) it changes from a distinct mathematical concept with a clear meaning to a metaphor with a broad semantic field" (p. 459), explanations based on physical analogs can be helpful (see, for example, Crano's, 1981 example of locating a radio signal by using multiple directional antennae). Social scientists suggested that social and psychological constructs, as well as physical objects, could be brought into clearer focus by using multiple measures from different vantage points with unique sources of error. The uses of triangulation quickly expanded to include triangulation of methods, sources, and theories as well as measures (e.g., Denzin, 1978, 1989).

Some researchers adopted the triangulation strategy wholeheartedly and launched large-scale, multi-investigator, multimethod, multisite, multimeasure studies of social problems (e.g., Lewis, 1981). The need to contend with conflicting results that arose from different methods and measures in the same study led to extensive discussions of the use of qualitative and quantitative research methods and data, across and within the same project (e.g., Reichardt and Cook, 1979; Tashakkori and Teddlie, 2003). Recently, the focus of discussion has shifted to triangulation among multiple paradigms (Greene and Caracelli, 1997; Greene and McClintock, 1985), multiple stakeholders, multiple analysts, multiple theoretical and value frameworks, and multiple targets within a study, a concept Cook (1985) calls "multiplism." Developments in analysis techniques also have promoted the use of triangulation, either at the measurement level, as in casual modeling (Joreskog and Sorbom, 1984), or at the method level, as in meta-analysis (Glass et al., 1981; Rosenthal, 1991).

Logic of Triangulation

Triangulation strategies can be contrasted with what Cook and Campbell (1979) termed "mono-operation bias." Whenever a construct is operationalized in only one way in a research study, the error attached to the method of operationalization, as well as any random error in the operationalization, is

inextricably linked with the true essence of the construct under consideration. This relationship is captured by the simple equation $X = T + e$, meaning that every data point (X) is composed of part True Score (T) and part error (e) (see, for example, Crano, 1981 for further discussion). With only one measure of a construct, the error caused by method bias, response sets, or investigator bias, to name but a few, cannot be disentangled from the true measure of the construct (see Shadish et al., 2002; Webb, 1978 for discussions of myriad types of error). By triangulating, or operationalizing the construct in several ways, the sources of influence on the data point can be disentangled, leading to a clearer understanding of the construct under consideration. Campbell and Fiske's (1959) classic discussion of the multitrait-multimethod matrix lays out a strategy for such specification.

The acknowledgment of the necessity of triangulation represented a maturing of the social sciences beyond the paradigm envy that previously had gripped the field (Crano, 1981). Early social scientists had attempted to gain acceptance and legitimacy by adopting much of the research trappings of the physical or 'hard' sciences. Operating from the positivist view of science (Cook, 1985), social scientists attempted to achieve parsimonious explanations of events and circumstances that would hold across times and settings, much as physical scientists were claiming to do. They sought the precise, well-calibrated measures, the elegant, critical experiments, and the straightforward analyses of the hard sciences. In some areas of research, this approach could be fairly successful. For example, a social scientist could operationalize 'response time' as 'the amount of time that is between stimulus and response,' with stimulus and response both being defined in terms of their operationalizations (e.g., 'the onset of the light' and 'pushing the button,' respectively). But as soon as the social scientists ventured beyond the laboratory and basic research, they discovered that mono-operationalization was inadequate to tap underlying relationships accurately and that simple analysis strategies were inadequate to describe the complicated interactive patterns in the data.

For example, social scientists quickly discovered that they could not define 'family size' as 'the number of people listed on the interview schedule under the heading Family' and be confident that they had captured the true essence of the construct 'family size.' Beyond the problems of deciding whom to list as 'family' (such as deciding what to do with people who are not biologically related but may be committed to the unit and people who are biologically related but rarely present), social scientists realized that some people are not going to report accurately, either because they misunderstand the question, because they are not aware of the true situation, or because they choose to report incorrectly.

To compensate for these problems with error and bias, researchers began to use multiple operationalizations of key constructs, and many claims of triangulation in research design are based solely on the use of multiple items to tap a construct. But, as Webb (1978) and others pointed out, using multiple instances of measures that share critical components of error does not improve the research much beyond identifying some random error. Finding that different measures or methods give the same results does not mean they are giving the right results; they might be giving results that are just similarly wrong (Erzberger and Kelle, 2003). To be most useful, multiple measures must have differing sources of error, including method error, and errors due to response bias and self-presentation, among many others. Campbell termed this important qualification the "heterogeneity of irrelevancies" (Brewer and Collins, 1981).

So, for example, having the same interviewer ask the same respondent 'how many people live in this house?' in a dozen different ways during the same face-to-face interview does not advance the construct validity of 'family size' very much. A respondent who really does not know that her daughter's boyfriend has been living upstairs will report incorrectly every time. A respondent who does not want to reveal that a cousin who is in the country illegally lives there consistently will not report that person as living in the house. An interviewer who consistently reverses threes and fives will do that every time. So repeated questioning only reduces the error associated with not understanding a particular question or with random errors made by the respondent or the interviewer. This is not to imply that reducing such error is unimportant, but rather that triangulation can be much more powerful when used across types of measures instead of within one method of measurement.

Partly in response to the shared error inherent in verbal responses, methodologists suggested the use of unobtrusive measures as a means of tapping constructs without the error inherent in verbal responses (Webb et al., 1966). Unobtrusive measures are not without error, but their usefulness comes from the fact that many of their error sources are different from the error sources that plague verbal responses (e.g., social desirability, response set). In one famous example, researchers measured the popularity of different museum exhibits by measuring the wear and tear on floor tiles surrounding different displays (Webb et al., 1966). Another researcher measured the level of activity among nursing home residents by measuring how dirty the adhesive tape attached to their wheelchair wheels became. Mosteller (1955, cited in Webb, 1978) measured the usage of various sections of the *International Encyclopedia of the Social Sciences* by noting how worn and dirty various sections of the book were. (Note to reader: Feel free to smudge, bend, and dog-ear this page.)

Extensions of Triangulation

The logic of triangulation was quickly extended to methodological orientation (quantitative or qualitative), research designs, treatments, theories, settings, and other aspects of the research enterprise. Denzin (1978) compared the pictures of reality obtained from different researchers using different methodologies at different times to the changing images within a kaleidoscope, sharing some common elements but greatly influenced by the circumstances of viewing. This is not to imply that there is no objective reality, but rather that it is filtered through the researcher's assumptions, research choices, and the factors unique to that point in time. In much the same way that Heisenberg pointed out to psychical scientists that the very act of observing or measuring a physical object can alter the reality of that object, social scientists were coming to appreciate the extent to which their own assumptions, choices, historical time

frame, and even mere presence influenced the data they collected.

Denzin (1978) outlined four basic types of triangulation: data, investigator, theory, and methodological. He further divided triangulation into the three subtypes of time, space, and person. Data triangulation across time refers to both time of the day as well as historical setting, which has been referred to as population changes associated with time (Campbell and Stanley, 1963). Some time effects are profound and obvious. For example, attitudes toward day care among women who engage in telephone interviews during the day might be very different from attitudes of women who respond in the evening (and presumably might have been at work during the day). Similarly, space could have obvious or nonobvious effects. Bosses and employees might have different views of the workplace space, but so too might workers near and far from the elevator.

A strength of triangulation is that the researcher does not need to understand completely the variation inherent in the data collection methods. In the same way that random assignment distributes error randomly across conditions in a true experiment even if the researcher is unaware of the importance of the error, triangulation captures and makes somewhat tractable irrelevancies of the research situation, even if the researcher is unaware of the importance of those irrelevancies. Of course, in the same way that true experiments can be strengthened if the researcher has identified problematic outside variables and blocked on those variables (i.e., randomized within levels of those variables), research designs can be strengthened if researchers can specify which outside factors might be problematic and can triangulate in such a way as to capture those irrelevancies. For example, if a researcher suspects that the age of respondent will relate to the variable of interest, the researcher should specifically select for a variety of ages among respondents and analyze the data specifically to examine age effects, instead of just hoping that triangulating over samples will capture those irrelevancies.

Beyond data triangulation, Denzin (1978) also advocates investigator triangulation, whereby multiple investigators bring their unique perspectives and biases to the research project. This is an acknowledgment that people, no matter how well trained, are not robotic recorders of social events. Again, if the researcher has a priori reason to suspect that some characteristic of the investigator, such as gender, might introduce error into the observations, care can be taken to select equal numbers of male and female investigators and to analyze for differences between the observations of men and women. But the use of multiple investigators should reduce effects of irrelevant observer factors, even in the absence of the researcher's awareness that such factors could be important. Of course, only irrelevant factors that vary among the investigators will be ameliorated.

In a similar vein, Denzin (1978) proposed that researchers approach projects from the perspectives of multiple theories, taking care to extend the scope beyond the theoretical orientation most comfortable for the researcher. He further suggested that rather than pit only two theories against each other in research, projects should be specifically designed to capture as many theoretical orientations as possible. Hypotheses derived from all of these theories could then be tested, and conclusions could be drawn about the relative strengths and weaknesses of the theories. The logic of triangulation is the same as with the previous examples: by using multiple theoretical views, the researcher is better able to bring the research question into focus.

Finally, Denzin (1978) described both within-method and between-method triangulation. Within a single method, such as a telephone survey, multiple items that are intended to tap the same construct can provide much clearer measures of the construct under consideration. Multiple items can be combined via a wide assortment of scaling techniques, ranging from simple additive scales to elaborate factor analytic scales. Again, the triangulation strategy does not result in items measured without error, but, rather, it allows the error that is not shared among the items to be identified and removed. The resulting scale should reflect only the 'true' component of the construct measured plus any error shared by the various items. For example, items that all cause the respondent to respond in a socially desirable manner will not allow the researcher to separate out social desirability components from components that actually tap the construct under consideration. But if some of the items have a response set bias and others do not, the use of multiple measures will allow the response set bias to be identified (within limits).

Because within-method triangulation can leave varying amounts of error inextricably linked to the key construct, researchers are encouraged to triangulate between methods (Brewer and Hunter, 1989; Campbell and Fiske, 1959; Cook, 1985; Hunter and Brewer, 2003; Reichardt and Cook, 1979; Webb et al., 1966). By combining methodologies as different as participant observation and survey research, for example, researchers can study processes under vastly differing assumptions, biases, and errors. For example, the *Reactions to Crime* Project (Lewis, 1981) involved participant observation, content analysis, telephone surveying, and in-person interviewing, all within one large framework. The approach used by the *Reactions to Crime* Project was sequentially multimethod, with the participant observation being completed first, followed by the telephone survey, and finishing with the in-person interviewing. With sequential multimethod work, researchers can use results from previous stages to inform design at later stages. Although this sequential strategy has strengths, Greene and McClintock (1985) pointed out that concurrent multimethod work, in which all methods are implemented at the same time, avoids contamination of one method with results from another and produces a purer triangulation.

Probably the most extensive elaboration of triangulation logic was provided by Cook (1985) who described research that involves multiple stakeholders, multiple data analyses, multiple definitions, multiple methods, multivariate casual modeling, multiple hypotheses, multiple populations, multiple settings, and multiple times. He stated that such multiplism allows the researcher to approximate the "ultimately unknowable truth through the use of processes that critically triangulate from a variety of perspectives on what is worth knowing and what is known. Triangulation requires generating multiple instances of some entity and then testing whether the instances converge on the same theoretical meaning despite the irrelevant sources of uniqueness that any one instance may contain" (1985: p. 57). Like previous writers, however, Cook was quick

to point out that "multiplism is no panacea, for we can multiply replicate the same mistake or the same parochial set of assumptions" (1985: p. 58). Although triangulation can be vastly expanded in scope, its strengths and weaknesses remain the same.

Limitations of Triangulation

Flick (1992) and Fielding and Fielding (1986) have suggested that proponents of triangulation mistakenly believe triangulation solves all construct validity problems. Miles and Huberman (1994) suggested that some researchers think it has near-talismanic properties. So is triangulation a magic wand for solving research problems? Or, at least, did (or do) some researchers believe so? To the contrary, early proponents of triangulation were sounding a warning about the inherent weakness of all measures, and the proposal to use multiple measures with nonoverlapping irrelevancies was an acknowledgment of the profound problems inherent in measuring. In a discussion of the distance between desired and achieved measures of social science constructs and hence of the hypotheses the operationalized measures test, Campbell concluded that "direct knowing, nonpresumptive knowing, is not to be our lot" (1969; p. 52). Therefore, one important limitation of triangulation is that it does not produce perfect measures.

If triangulation does not ensure a perfect reflection of reality, why is it touted as such a boon to research? Researchers have suggested various metaphors to explain the gains from triangulation. Erzberger and Kelle (2003) used a puzzle metaphor to illustrate the gains from triangulation. Each piece of research with a different approach, method, or measurement provides another piece to the puzzle that represents reality. The pieces all together give us a more complete picture of reality than any one piece by itself. They suggested triangulation results not so much in validation as in extension of our understanding. Similarly, Flick (1992) suggested triangulation produces alternatives, rather than validation of the original study, while Olsen (2004) suggested triangulation is not aimed at providing validation but at increasing understanding. Research based on different assumptions and methods can produce results that conflict without either being invalid. Finally, Cresswell et al. (2003) offered the metaphor of maps created by results that stand for the underlying process but that are not to be conflated with the actual process, in the same way that a map is not conflated with the landscape it describes.

Another limitation inherent in the triangulation strategy is that time, finances, and respondent goodwill conspire to prevent a researcher from triangulating on all the constructs in the research program. One can easily imagine how attempting to triangulate on theoretical orientations, research designs, and measurement strategies could lead quickly to a program of research that could never produce a single result, because it never could be completed. The successful researcher must therefore choose where to invest his or her triangulation resources, and the soundness and usefulness of the research outcomes depend to a large extent on the wisdom of those choices during the research design phase.

The amount of effort a researcher chooses to devote to triangulating on the construct should reflect both the importance of that construct for the research question and the level of difficulty in achieving a good measurement. For example, if age is a crucial variable for a research question, investigators might invest extra resources in accessing birth records as well as asking for age and birth date in a survey. If age is less crucial to the question at hand, the researchers might decide to rely on the verbal replies only. Similarly, a true experiment performed in a laboratory might prove adequate for testing a hypothesis about visual processing, but researchers investigating hypotheses about reactions to stress might need to invest in multiple methods to achieve clarity about the processes under investigation.

The researchers' choices about constructs for triangulation resources can have significant effects on the results of the research. For example, if a researcher believes Family Income to be a more important construct in explaining school achievement than Parental Education Level and consequently devotes more effort to triangulating on the measure of Family Income than Parental Education Level, analyses might well reveal a stronger relationship between School Achievement and Family Income than School Achievement and Parental Education, because Family Income was more reliably measured. If the researcher had made the opposite assumption and had devoted more resources to measuring Parental Education than to Family Income, the results might well have shown the opposite effect. The utility of triangulation, therefore, is limited by the soundness of the researchers' initial decisions about resource allocation.

Advances in Triangulation

The logic of triangulation is inherent in both structural equations modeling (Joreskog and Sorbom, 1984) and meta-analysis (Rosenthal, 1991). Structural equations modeling (SEM) is an analysis technique that relies on multiple measures (manifest variables) of some underlying construct (latent variable). Researchers specify which manifest variables relate to which latent variables, and the analysis strategy pulls out common variance among the manifest variables that feed into a latent variable. Variance in the manifest variable that is not shared with the other manifest variables for that latent variable is identified as 'error.' Error terms can be allowed to correlate with other error terms. This is a sophisticated extension of the logic used by Campbell and Fiske (1959) in their explication of the multitrait-multimethod matrix. They pointed out that only part of what researchers are measuring is the key construct they are intending to measure. The rest of the measure includes method variance, random error, and possibly other types of error and bias. SEM requires researchers to identify error explicitly in their models, which makes very clear the frailty of any one measure in isolation. In addition, SEMs show clearly how error terms from similar measures correlate, increasing researchers' awareness of such measurement effects. Recently, this technique has been widely employed and has been used to study spirituality (Sandage and Williamson, 2010), traumatic stress and avoidance (Briere et al., 2010), and early childhood anxiety (Mian et al., 2011), among many other topics.

In a similar vein, meta-analysis exploits multiple studies, with multiple operationalizations, multiple investigators, multiple methods, multiple sites, multiple populations, and many other differences to arrive at a summary statistic that reports the strength of underlying relationships across studies. Instead of requiring one researcher or research team to approach a research question from multiple perspectives, theories, and methodologies, meta-analysis capitalizes on natural variations among research programs to achieve triangulation. A main benefit of meta-analysis is that methodological variation can be built explicitly into the analysis. For example, in a review of the research on environmental and genetic effects on aggression, Miles and Carey (1997) reported that observational measures in laboratory studies showed no genetic effects and strong environmental effects, while self-report and parental rating measures showed both genes and environment to have strong relationships with aggression. Because variance associated with particular methods and measures can be explicitly analyzed in meta-analysis, the increased understanding afforded by triangulation strategies becomes apparent. And the conflicting results from different methods, far from being a nuisance or drawback to triangulation approaches, are rich clues to contingencies that need to be brought to light if social research is ever to reveal fully how these processes operate (Cook, 1985). This method has gained acceptance across a wide range of content areas, including studies of birth order effects in major league baseball (Sulloway and Zweigenhaft, 2010) and religiosity and self-enhancement (Sedikides and Gebauer, 2010).

The importance of triangulation also has been revealed by the prevalence of statistical interactions in social research. Evaluation researchers and others who study social problems rarely find that simple, main effects capture the richness (some would say messiness) of the world beyond the research laboratory (Cook, 1985). Evaluators no longer ask, "Does this work?" but, rather, "For whom does this work, in what settings, with what constraints?" The prevalence of interactions pushes researchers to branch out to different populations, different time frames, and different methods, in other words, to triangulate across many factors in the research setting.

Social research has come a long way from the days when researchers sought pure measures, elegant, simple designs, and straightforward analysis strategies. The norm for social research now is multiple measures, elaborate multimethod design, and analysis strategies that clearly indicate the multiple causation and interactive patterns apparent in the social world. In no small part, this march toward increasing complexity of the research enterprise started with early explications of the logic of and necessity for triangulation.

Abstract

Today, a largely defunct comparative concept from the colonial era, the term tribe once designated allegedly 'primitive' local medium-sized social entities with some territorial rights. From its contexts of emergence, the term often attained largely pejorative connotations including nonhistorical qualities of secluded stability. The term still is in current usage for legal and political reasons in many parts of the world, although sometimes being confused with ethnic groups and other more appropriate notions. In ethnoarchaeology, history, and anthropology, it may continue to serve as a scientific concept for certain descriptive purposes if liberated from its ideological connotations.

The notion of tribe emerged in the seventeenth and eighteenth centuries in the course of colonial expansion. Abandoned increasingly by the majority of anthropologists from the middle of the twentieth century onward, the term nevertheless lived on in certain anthropological constructions, until waves of criticism dealt final blows to a concept that is now largely defunct as a general comparative category. Those anthropologists and historians who retain the contested concept of tribe use it mainly as an ethnographic tool and as equivalent to certain vernacular or national legal terms referring to local conceptions of collective sociopolitical identity, while agreeing that a precise general definition is almost impossible. This results in loose working definitions which see tribes as medium-sized, centralized, or acephalous entities displaying a combination of basic characteristics:

1. They are usually associated with a territory, homeland, or tribal area, while using nonterritorial criteria to distinguish between members and nonmembers. The degree of control of the tribal territorial base, and its extension and location tend to change as a result of struggles with states or other opponents. To the outside world, access to territorial usage appears to be confined to members of the tribe, although neighboring groups and superior authorities may also enjoy rights of usage, of tribute, or of taxes. Internally, access to territorial usage may be differentiated according to gender, age, status, wealth, and other aspects of power.
2. Ideologically and socially, tribal members usually share some dominant idiom of common origin, such as descent from a single ancestor, emphasizing group cohesion over outside interests and internal differentiation. This may also serve to legitimize a preference for 'marrying within the tribe,' which in practice, however, is observed far less often than it is upheld in theory. On the contrary, some amount of intertribal and interethnic marriage is indispensable to ensure all kinds of (political, economic, social) alliances with other groups.
3. Although part of the tribal population live more or less permanently in the tribal territory, a considerable portion may live in the world outside. Ritual and kinship ties and obligations are enacted to ensure and strengthen intimate networks among 'home' groups and 'outside' groups, serving as one among several inventories of group adherence within a wider world. In the course of these interactions, tribal group membership may change in many ways: individuals or groups may enter or leave a specific tribe and whole tribes may also collapse or be created.

Tribes and Colonialism

The concept of tribe dates from the earliest phases of anthropology's history, carrying assumptions that are now being criticized and questioned inside and outside academia. Most colonial governments used the term for specific practical interests in administration and dominance while often constructing 'tribes' themselves to that purpose. Beyond these practical interests, colonial settler regimes also valued the term ideologically, since it tended to portray local groups as 'backward' and 'primitive,' which helped to justify a colonial 'mission' of development and civilization. For similar reason, many postcolonial governments and national elites reject the term as being counterproductive to their own claims toward national unity, progress, and modernity.

During decolonization, the term tribe therefore attained a largely negative and pejorative meaning in dominant opinions in many parts of the world. In public discourses concerning these areas, the terms 'ethnic groups' or 'indigenous peoples' are usually preferred to 'tribes,' although the latter usually designates smaller groups. Legal terminology, nevertheless, may continue to apply the term, and in many regions even native speakers may use it with dignity.

In parts of central and western Asia, however, as well as in North Africa, particularly in those areas influenced by Islam, the term tribe and its local equivalents have never had a predominantly pejorative meaning. On the contrary, the term here is usually associated with notions of pride and autonomy, of honor, and of some independence from colonial and local states. Also, notions of 'indigenous' or 'ethnic' groups do not apply well to many of these specific ethnographic contexts. Both of these factors are therefore responsible for the continuing, stronger importance of the term tribe in academic and public discourses inside and about these regions.

Tribes in Anthropology

Before anthropology's emergence, travelers, missionaries, and scholars had used the concept since the seventeenth century in

describing those indigenous peoples whom European powers were about to colonize. Ancient Middle Eastern and Graeco-Roman literature served as sources of reference to depict the newly colonized peoples as representing some kind of forerunners to the 'advanced nations,' equivalent to the *tribus* of the ancient Mediterranean world. The construction of this 'forerunner' image could follow either more sympathetic lines, by emphasizing the enlightened aspect of a noble savage who basically was 'like us,' or it could enhance the more discriminating image of backwardness.

Both ideas presupposed a search for origins, taking European culture as the climax of humanity. In its basic conceptualization, a tripartite world had thus already been constructed, which early anthropology inherited and further elaborated. 'Primitive' cultures consisted of foragers, and pastoral and agrarian 'tribes,' whereas 'oriental' cultures were associated with agrarian states, cities, and with writing. Anthropological evolutionism (e.g., Morgan, 1877; Smith, 1903) elaborated and specified this conceptual inventory, in which, by and large, tribes constituted the decisive transitory stage between early hunters and gatherers and the rise of agrarian states. In a long-term archeological perspective, this may still serve as a valid distinction for certain regions and periods, if liberated from its earlier ideological underpinnings.

Classical anthropological evolutionism collapsed, however, because the increasing body of empirical data showed the failure of any general laws of development, including those regarding tribes. By contrast, the new school of 'historical particularism' or cultural relativism that came to dominate US anthropology around 1900 emphasized the situated, fluid contextualization of each local and tribal group. While this prepared the ground for an empirical orientation that is still valid at the time of writing, the inherent relativism rejected almost any comparative meaning for the concept of tribe. The comparative aspect, by contrast, was elaborated explicitly by anthropological functionalism, largely of British and Northern European provenance. In an earlier variant, Evans-Pritchard (1940) outlined the 'structural relativity' of many tribal group relations around a basic social organization of 'nested' group segmentation (Barth et al., 2005).

In fact, such segmentary relations do represent a dominant model among many local (tribal) groups in Africa and Asia, often being expressed in the prevailing idiom of unilineal genealogy. In these terms, the 'descendants' of one ancestor are contradistinguished, under some conditions, against those from another ancestor, while under different conditions the same group of descendants may split up and oppose each other. Mutual threat, equality of group status, and reproduction of social equilibrium are inherent to this indigenous model, taken up and reconstructed as an anthropological model. Major critiques, however, pointed to implications of timeless stability and secluded cohesion, which to some degree corresponded well with the ideologies of late colonialism.

Gellner (1981, 1990), who was most influential in transferring the segmentary model from sub-Saharan Africa to North Africa and the Middle East, reacted to some of that criticism with an increasingly more refined variant that to an extent absorbed Ibn Khaldun's reasoning on the topic. According to Gellner, Middle Eastern tribal societies interact constantly out of the peripheries with each other and with the states in their centers, sometimes being absorbed or reshaped in the course of these interactions, and sometimes themselves destroying and recreating central states. These processes always promote tribal centralization, inequalities, and tendencies to fusion and fission, which are simultaneously more or less countered by applying the local segmentary model. Jamous (1981) showed in more detail than Gellner how these tendencies to feuding and conflict may be embedded in idioms of 'honor and shame.' His account illustrates how these tensions, which favor the emergence of ephemeral 'big men,' are countered through mediation by third parties, who in many cases are of superior, holy status.

While Marxist, late functionalist, and neoevolutionist critics (for example, Fried, 1975; Godelier, 1973; Southall, 1970) were the first to radically criticize current ideas about tribes in the 1960s and early 1970s, a few anthropologists held on to a general, neoevolutionist conception of tribe. Sahlins (1968) advanced a distinction between acephalous 'segmentary lineage' tribes, more centralized 'chiefdoms,' and 'conical clan' intertribal hierarchies. On the other hand, in Middle Eastern studies the concept gained new respect in the Gellner/Jamous variant, by its consideration of formerly neglected aspects, such as historical dynamism or certain ideological, political, and social factors. A second wave of academic criticism throughout the 1980s and early 1990s came from feminist, postmodern, and postcolonial writers, who deconstructed profoundly the colonial legacy in the concept, and exposed the complete negligence of economic factors and of female lives in the 'tribal' model (Abu-Lughod, 1986; Gilsenan, 1996).

Current Readings

In present discussions, the debate is therefore oscillating between complete rejection of the term 'tribe' and its more or less restricted usage for specific times and regions. Most scholars, however, would agree that the concept is obsolete as a general comparative category outside particular areas. In addition, historical and archeological research might continue, for parts of northern Africa and Asia at least, to consider some conception of tribe as useful (Dresch and Heykel, 1995). Such a restricted, critical elaboration of the concept would, of course, have to take into account seriously previous critiques.

Some of the criticism was creatively synthesized by Bonte and Conte (Bonte et al., 1991). Their approaches basically privilege historical change over repetition, interaction over system, status rivalry over group equality, and marriage and other forms of alliance over descent and ancestry. This helps to outline internal hierarchies among local tribal groups, including the constraints and fields of agency encountered by women, while demonstrating simultaneously how tribal organization is instrumentalized to defend states, to support struggles for central power, or to engage in civil war for various interests.

The postcolonial condition seems in fact to encourage such a restricted, critical elaboration of the concept, rather than discarding it totally. Recent attempts to substitute the term by other European alternatives such as 'principality' (Sneath,

2007) or 'community' (Blumi, 2010) offer few analytical advantages while in fact empirically ignoring what they claim to rephrase. Under the conditions of advanced globalization after the Cold War, and of increased competition within as well as among weakened local states (ranging from Mauritania and Somalia to Afghanistan and Bangladesh), ideologies of ethnicity, but also of tribalism, are gaining significance in many local arenas. It would amount to a strange paradox if critical researchers limited themselves defensively to deconstructing completely the concept of tribe, while many parts of the world in fact go through retribalization of some sort. An active reformulation where empirically appropriate might be the more productive alternative. To that purpose, ideological movements of 'tribalism' will have to be distinguished more clearly from 'tribes,' parallel to the concepts of nationalism and nations. Tribalism and its activists strive more or less successfully to create imagined communities of tribes, with ideological pretexts of 'origins' and of 'cohesion' that serve competition over power and resources. In this perspective, anthropologists are as critical and skeptical about tribalist ideology as they are with regard to nationalism. All the same, they would not deny from the outset that nation states and tribal groups may exist; rather, they would insist on exploring the interrelations between such local entities, their ideological activities, and the world around them.

Trickster Ethnography

Abstract

The trickster figure in anthropology, folklore, and religious studies has been used to examine how a society understands itself through the study of transgressive characters and local notions of creativity. Tricksters are fundamentally dual raising ontological and epistemological questions about rationality, morality, temporality, and meaning. Tricksters have been important signs of irreverence and inversion and shift between tellers of mythic tales, world makers, culture heroes, selfish hustlers, and agents of change who playfully navigate violent worlds. They are linguistic and ritual mediators, translators standing at the crossroads of mythic and historic time, spiritual and social space, animal and human subjectivities. As tricksters have been identified across various societies, the category of trickster at times tells us more about a process of reductionist inquiry and the anthropological desire for analytic categories than about the lived worlds in which these diverse figures live.

The trickster figure is a mediator who stands on the border between realms, showing how a society understands itself by embodying its transgressions. In anthropology, folklore, and religious studies, identification of the category of the trickster has been a way to fit various apparently transgressive characters and social phenomena into a model of social cohesion. This speaks both to the history of anthropology as well as to fundamental ontological and epistemological questions regarding rationality, duality, temporality, and meaning raised in ethnographic inquiry. Tricksters are fundamentally dual. They are important signs of irreverence and inversion and shift between tellers of mythic tales, world makers, culture heroes, selfish hustlers, and agents of change. In a sense, tricksters have provided a way to theorize the social relevance of creativity. They are linguistic and ritual mediators, translators standing at the crossroads of mythic and historic time, spiritual and social space, and animal and human socialities. The trickster literature speaks to recently renewed debates in anthropology about the relationship between nature and culture as well as difference and translatability.

Coyote, Raven, and Hare in various Native American mythic traditions have been characterized as tricksters igniting scholarly debates about how one character can be both "culture hero" and "selfish-buffoon." Eshu, the Yoruba trickster and Legba in Dahomey are trickster deities that oversee markets and crossroads and mediate spiritual divination and all sorts of risk. The Tortoise in Yoruba (Owomoyela, 1997) and the Akan Spider trickster Ananse are central to mythic storytelling and mediators of social, linguistic, and spiritual transformations. Loki from Norse mythology is a shape-shifting god of mischief. In Greek mythology, Prometheus is a trickster who fooled Zeus to give mankind fire. The Greek Hermes, emerging from Sanskrit and Aryan traditions and later reincarnated as the Roman Mercury, is a trickster as messenger of the gods, inventor of the arts, and patron of thieves. Odysseus is a trickster in his wonderings and wanderings. European festivals of Rabelaisian inversion have been seen as invocations of the trickster (Davis, 2006). B'rer Rabbit in African-American folklore is a trickster who gets in and out of trouble through nimble thought. The Malay "mouse deer is the stereotypical 'trickster' figure: a small and weak but agile creature who survives and triumphs over far more powerful beasts by his wits, his deceit and his cunning" (Scott, 1987: p. 300).

Considering the disparate types who have been called tricksters and their varying social relevances raises how this figuration demarcates a coherent analytic category by uniting a menagerie of superficially similar renegades, messengers, and hustlers. Trickster facilitates a sometimes sloppy, sometimes productive slippage between social analysis and the reflexivity of lived experience. Fundamentally, trickster's various permutations create an analytic category that reveals various social signs of self-consciousness. In doing so, it unites a disparate set of characters and tales showing how ethnography, textual analysis, and social theory make sense of sociocultural reflexivity.

As tricksters have been identified across various societies, the category of trickster at times tells us more about a process of reductionist inquiry and the anthropological desire for analytic categories than about the lived worlds in which these diverse figures reside (Beidelman, 1980). Early theories of tricksters see them as amoral figures who are nevertheless fundamental to the production of social norms in their roles as extraordinary creatures who unwittingly make the world habitable for humans. Trickster has been part of the development of central strands of anthropological theory in relation to comparative religion, folklore, ritual theory, Boasian notions of culture, structuralist analyses of myth, British structural-functionalism, and theories of power and resistance. Analysts often blur an understanding of trickster as a locally identified character in mythic texts and folktales read as socially sanctioned representations of self and as a universal archetype defined by certain types of ambivalent destructive – creative behavior, selfishness and artful hustling. He – and it is certainly a highly gendered, masculine character – provides us a way to examine the changing ways researchers have theorized coherence and rationality and the relationships of representations to culture.

Anthropologists, folklorists, and comparative religion scholars have identified trickster as a figuration for organizing a set of characters and stories from disparate times and places. The category coalesces in the late nineteenth and early twentieth century through interest in Native American folklore and studying

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12227-5

so-called primitive religions as part of comparative religions projects that led to mid-twentieth century interest in identifying the archetypes fundamental to human existence through the folkloric. In the late twentieth century, analysts – most of them relying upon reworked data of older folklorists and anthropologists – see the trickster as a figure of subversion and innovation arising particularly among underclass groups and within historical conditions of inequality. Tricksters and trickster-like behavior gave those on the margins ways to subvert and invert social norms and address power from within through parody and double-voicing. Tricksters in this guise focus on selfish desire, which becomes a form of agency. Rather than seeing them as mythological producers of social order through the inverted representation of social values, they become actors in ongoing, historically specific resistance struggles that address structural inequality. The oscillation between ideas of the trickster as a mythological cultural mediator and as renegade hustler shows how the same evidence can be used to make contradictory arguments while appearing on the surface to be reinforcing the sociohistorical relevance of a general category.

Early twentieth-century ethnographic and folkloric studies take tricksters as representations of specific cultural and mythic systems. The trickster proves a fruitful link between anthropology, religious studies, and psychoanalysis as an archetypical character that links a cultural logic through comparative analyses, to more profound, universal aspects of the humanity. African tricksters tend to be seen as linguistic and ritualistic mediators of human relations. As in Native American examples, they are significant in how they create social relations and values through rituals and signs of inversion. In both areas, analysts struggle to make sense of the relationship between what they see as the contradictions of tricksters: as selfish amoral hustlers and creative heroes. Since the actions that analysts see as contradictory do not seem to concern the societies under consideration, moral coherence and desire for rational cosmology reveal more about the analysts than the people under consideration.

While early studies of Native American and African societies imagined tricksters as figures of traditional cosmology, later scholars presented tricksters as transgressive, historically situated characters that speak to and about power, representing the political strategies of underclass peoples. Zora Neale Hurston (1935), of course, talks of tricksters in a variety of ways, taking the Boasian interest in myth and folklore into understandings of America's life. Her work implicitly grounds the trickster as a figure of collective memory and power struggles, rather than sign of cultural order. Tricksters abound in her tales of African-American and Caribbean politics, folklore, and life. Men and women trick each other. God and white people trick black folks into accepting their historical burdens of labor. Black people in America hustle and charm white society in order to survive. Hurston the teller of tales is a trickster slipping between categories, finding and elaborating different stories for different audiences. For Hurston, trickery is a culturally-historically specific source of pleasure, power, and survival. However, in the hands of others, the trickster becomes a general metaphor applicable to any social type who exhibited irreverent hustler-like behavior. As it is generally applied, the category removes characters from the nuances of social context for the sake of analytic explanation. Tracing how the trickster story has been told by scholars provides insight into ethnography's changing relationship to comparative techniques, mythic logics, ideas of creativity and transgression, and the entanglements of history with culture.

Native American Mythology from Culture to Structuralism

The trickster emerges from late nineteenth and early twentieth century collecting of Native American folkloric-mythological tales. The study of Native American religion and cosmology through mythic tales provides missionaries, anthropologists, and amateur ethnographers' ways to understand the so-called primitive cultures as they face erasure through the encroachment of white civilization and religious conversion. In documenting disappearing native cultures, myths are seen as relatively pure representations of archaic cultures giving insight into the nature of humanity. The trickster figure is central to many of the tales collected. Native American tricksters tend to be the Coyote in California and the Plains, the Raven in the Pacific Northwest, the Hare and Rabbit among Algonquian speaking groups, and others in the Northeast (cf Carroll, 1981). Tricksters tend to have both human and animal characteristics. They live in both mythic and human time.

Paul Radin's *The Trickster: A Study in American Indian Mythology* (1956) is the most influential anthropological study of the trickster, shaping the subsequent popularity of this term. In 1908, Radin enlisted a key informant to find an old man who knew what were understood as authentic versions of the Winnebago trickster cycle, uninfluenced by rising proto-Christian Peyote cults. The tales were purportedly recited in the proper ritual context written down and later transcribed by Radin. The trickster cycle of the Winnebago tells of Wakdjunkaga's exploits in a self-contained narrative focused on the making of the social world. Radin provides analysis and interpretation in a separate essay. The 1956 edition includes summaries of the trickster cycle of Sitconski, the Assiniboine trickster recorded by Robert Lowie (1909) of Raven, the Tlingit trickster recorded by J.R. Swanton (1909), and the Winnebago Hare cycle. It also includes two essays, one by Karl Kerenyi comparing the trickster to Greek mythology and one by C.G. Jung exploring the trickster as archetype.

In Radin's account, the trickster is fundamental to Native North American societies. Wakdjunkaga means "the tricky one" in Winnebago (1956: p. 132). In the cycle of tales, Wakdjunkaga is first removed to a primitive state, as an "amorphous, instinctual, and unintegrated being" without ethical values, social awareness, or self-consciousness. In contrast, the world of nature is represented as "conscious" aware of Wakdjunkaga and his actions (1956: p. 133). Wakdjunkaga's body, emotions, and actions are disordered. The process of the Winnebago trickster cycle, then, orders and develops the trickster out of isolation, creating his body through a social logic. His body is literally shaped with penis and intestines and left and right hands being arranged appropriately. Wakdjunkaga seems at times to strive for "full psychical and social–ethical maturity" though does not seem to achieve it (1956: p. 134). He does not belong "in the world of men but to a much older world" (1956: p. 148). In Radin's analysis, the experience of emotions like

grief and fear lead to self-awareness. The tales describe the trickster breaking myriad taboos and shifting between social categories. For Radin, the representation of the breaking of taboos is shocking for participants, and provides a way of educating, shaping the trickster; joking, craziness, and inversions of social norms lead Wakdjunkaga to be "suddenly represented as a good citizen, as a thoroughly socialized individual" (1956: p. 139).

Many of his activities revolve around inverted and intense relations between sex and violence. Lowie records that the Assiniboine trickster dresses as a woman to marry a young man, and then fools him into thinking he is pregnant by putting a fox under his dress. The trickster breaks taboos by having sex before going on the warpath. The character shifts between being a man and a woman and seducing and having sex with men and women. The Winnebago trickster has a vulva at one point and gives birth to a child by a chief's son. Radin describes how the Winnebago cycle tells how the trickster's huge penis is separable from his body and slung over his shoulder. Subsequent commentators are struck by the ways that the trickster's penis is cut into pieces and made into human form (Hyde, 1998: pp. 28–31). Trickster chases the chipmunk and probes a hollow tree with his giant penis to get him. Chipmunk chews his mobile oversized detachable organ into a human sized one in the proper place on his body with the pieces of his penis cast onto the land and water to "make objects for human beings to use" like potatoes, turnips, and rice (Radin, 1956: p. 39). The Winnebago cycle ends as Wakdjunkaga makes the Mississippi River safe for people, killing and eating "beings that were molesting the people" (Radin, 1956: p. 52). He tells the waterfall to move stating "I am telling you that the earth was made for man to live on and you will annoy him if you stay here. I came to this earth to rearrange it" (Radin, 1956). After wandering the world and getting in various altercations with various people and animals – polecat, mink, woodpecker, coyote – he eats a final meal near the juncture of the Missouri and Mississippi rivers, his buttocks and testicles made impressions in the rock, and his kettle and bowl also remain. He then leaves this world. "Under the world where Earthmaker lives, there is another world just like it and of this world he, Trickster, is in charge" (Radin, 1956). Radin's analysis revolves around questions of morality and motivation probing the human psyche and the social world for the significance of the trickster as a representation of an archaic culture that gives insight into broader issues of humanity. Trickster makes the world safe and habitable for humans but often not out of altruistic interest in humanity but rather through capricious, unthinking action (cf Basso, 1987: pp. 4–8).

The analytic category of the trickster emerges out of the nineteenth century debates about the comparative study of Native American religions as they evolve through a concern with the moral implications and abstract symbolism of myths in so-called archaic societies. Daniel Brinton focused on "Hero Myths" arguing the goal of comparative mythology was to discover "the influence of the myth on the individual and national mind, on the progress and destiny of those who believed it, in other words, its true religious import" (Brinton, 1882: p. xi). Countering prevailing racist notions that "savage races" did not have religion he argued "what appears cruelty, puerility, or obscenity assumes a very different aspect when regarded from the correct, the native point of view, with a full knowledge of the surroundings and the intentions of the myth-makers themselves" (Brinton, 1890: p. 103). Others had argued that hero-gods were actually distorted tales of "chiefs of tribes at some undetermined epoch" and that "tribes" worshiped "external phenomena" and nature (Brinton, 1882: pp. vii & xii). Instead Brinton argues that the Native American hero-god "human in nature, benignant in character, loved rather than feared, and that his worship carried with it the germs of the development of benevolent emotions and sound ethical principles" (Brinton, 1882: p. xii). In the assumed evolutionary hierarchy of societies, studying "primitive peoples" focused on myths as precursors to more advanced theological thinking, which Brinton saw in animal myths, representations of the inanimate as animate and the irrational as rational (Brinton, 1882: p. 21). He compares mythic hero-gods from Native American religions like the Mexican Quetzalcoatl with "Old World mythologies," like those of the Greek Hermes, inventor of the alphabet, music, and the arts, messenger of the gods, and patron of thieves (Brinton, 1882: p. 31). He examines tales of the Algonkin Michabo, The Giant Rabbit, and the Iroquois Ioskeha. For Brinton, hero myths stem from the personification of natural phenomenon and while he argues Native American peoples are not as advanced as Western societies, they value "individual virtue" (Brinton, 1882: p. 235) and the "moral evolution of the nation proceeded steadily from its mythology" (Brinton, 1882: p. 239). Brinton uses Native American hero myths to argue the influence of Christianity and Europeans corrupted and destroyed rather than fostered Native American thought, morality, and virtue, which had its own particular evolutionary track. For Brinton, "the assumption of the psychic unity of mankind underlies all his work in the field of comparative religion and impelled him to argue for the spontaneous origin of religious parallelisms" (Weeks, 2002: p. 5).

Debates about the links between religion and morality and cultural evolution remained central to the study of mythic heroes. Brinton, countering established evolutionary racist theories which describe non-Western people as incapable of abstract thought, argues the selfishness of culture heroes is probably the result of "a gradual deterioration of a purer more primitive form of the myth, and that the more vulgar tales are later additions" (Boas in Teit: p. 4); that is, ancient altruistic sacred tales of creation are layered with more recent profane elements of selfish egotistical behavior.

In the introductory essay to James Teit's 1898 *Traditions of the Thompson River Indians of British Columbia*, Franz Boas mulls over two aspects of "transformer myths" namely the seeming contradiction between the altruism of culture heroes and the selfishness of tricksters that in many tales are, in fact, manifest in the same character. Often, these supernatural human-animals only aid humanity by accident. Humans, in fact, appear incidental to the protagonists of the stories. To folklorists and analysts of comparative religions this is a problem as it contradicts assumptions about moral being.

The lack of concern for humanity in hero myths is a central issue; interpretation revolves around the seeming moral contradictions between a culture hero and the selfish-buffoon. Franz Boas and his students argued that the culture hero is common in Native American myths, describing a "prehistoric era" when "there was no clear distinction between man and

animals" (Boas in Teit: p. 4). The culture hero "gave the world its present shape, who killed monsters that infested the land, and gave man the arts that make life worth living" (Boas in Teit: p. 4). But these figures are not altruistic or allies of humanity. Boas takes an opposing view to Brinton, arguing that the altruistic side of transformer myths develops "with the progress of society. …The higher the civilization of the tribe, the more sharply, it seems, is the line drawn between the culture hero and the trickster" (Boas in Teit, 1898: p. 10). The more developed the altruistic sensibility is, the more there is a contradiction between tricksters and culture heroes splitting the transformer in two. This contradicts Brinton's idealized view that civilization and contact corrupt primitive society and argues for a historical understanding of myth that acknowledges the interplay between the mutually constituted development of ritual and myth and the natural environment and the adoption of various "foreign" tales.

For Boas, detailed historical analyses of myths give insight into outside influences, showing how "foreign and indigenous material is interwoven and worked into a somewhat homogeneous fabric" (Boas in Teit: p. 18). Here, understanding the origins of transformer tales is important because these stories reflect how a culture refracts environment, geography, social organization, and kinship. For Boas, discrepancies between rituals and myths can reveal "survivals," imported images and stories from other cultures and older traditions, giving insight into changing social conditions. Examining historical change reflected in myth can yield an accurate understanding of cultures. As myths are reflections of archaic thought and the ways that people make sense of nature and the changing social conditions in which they find themselves. Boas' interest in myth is a Hegelian lament about something that appears only in its erasure: "It would seem that mythological worlds have been built up, only to be shattered again, and that new worlds were built from the fragments" (Boas in Teit: p. 18). Franz Boas and his students argue for the study of material and symbolic aspects of life in order to form rich ethnographic descriptions of a culture in context. This is a critique of older forms of ethnographic inquiry that sought to compare elements of societies based on surface similarities and assumptions about racial evolution. Instead Boas contends meaning of signs and objects can only be understood through situating specific elements within a culture and its internal logics. Only through the examination in detail of particular cultures can the comparative relevance of social analysis be realized and turned into more abstract generalizations. Studying Native American cultures was a way to record more "primitive," disappearing cultures that, because of their evolutionary proximity to "our" origins, offer comparative insight into the nature of humanity. At the root of the Boasian interest in the culture hero, transformer, and trickster was a concern for the specific epistemological relations between myth and culture.

For Radin, as for his teacher Boas, the trickster has a "twofold function of benefactor and buffoon," which is the "outstanding characteristic of the overwhelming majority of trickster heroes wherever they are encountered in aboriginal America" (1956: p. 124). Wakdjunkaga is significant in preparing the world for humanity and in mediating social being, though in the process can never fully inhabit this world as he straddles the supernatural, the mythic, the archaic, and the lived world. The development of social awareness and self-consciousness is central. While on one level the selfishness and violence of the trickster is amoral and unaware, it, in fact, produces the world through the creation of awareness; his actions constitute self-sacrifice as a form of world-making. Wakdjunkaga transgresses norms and tempts and tricks others, in the process creating social boundaries and categories. Radin points out that the trickster entails multiple interpretations among Winnebago, and its tales reflect social and historical change and the influence of multiple outside sources. Though ultimately the tales are interpreted as about creating and reproducing a normative idea of social life and of good citizenship.

Ultimately for Radin, the trickster is the symbol of an "Archaic and primordial past, where there as yet existed no clear-cut differentiation between the divine and the nondivine … His hunger, his sex, his wandering, these appertain neither to the gods nor to man. They belong to another realm, materially and spiritually, and that is why neither the gods nor man known [sic] precisely what to do with them" (Radin, 1956: p. 168). The trickster in this guise is beyond good and evil, does not fit properly into any time, any type of being, god, human, or animal, or any social category or place. He is inside and outside of each person, responsible for making the lived world but not able to fully inhabit it (Radin, 1956: p. 169).

Radin's account of the Winnebago trickster shapes many scholarly understandings of the character. For Jung the trickster, as Radin outlines him, is a mythical figure that represents and comes out of our inner psychological order. "In his clearest manifestations he is a faithful copy of an absolutely undifferentiated human consciousness, corresponding to a psyche that has hardly left the animal level" (Jung in Radin: p. 200). Jung maps psychic development of humanity onto the evolutionary development of cultures seeing the Winnebago trickster as a window into the primitive mind, which is the root of all human psychology but more clearly accessed in the so-called primitive peoples. He links this trickster to other characters and rituals of inversion in medieval Europe such at the fools' feast. The trickster is manifest in the shape-shifter, poltergeist, and shaman. For Jung, the trickster is "an archetypal psychic structure of extreme antiquity … a faithful copy of an absolutely undifferentiated human consciousness, corresponding to a psyche that has hardly a primitive or barbarous consciousness … a picture of itself on a much earlier level of development" (Jung in Radin: p. 200). But, for Jung, the presence of the trickster in numerous figures in contemporary life is not simply a holdover; it has a function. The trickster, as with all archetypes and psychologically relevant figures, is a way the psyche is speaking about itself. It provides a form for reflection. The trickster in some ways recalls the savior figure. As people move forth from the archaic origins of the trickster myths, the trickster provokes self-consciousness. He is like a shadow of both the collective and the individual, a negative figure, a reflection of consciousness though one that is contradictorily highly unconscious because of his unstable proximity to the self. For Jung, ultimately the trickster plays a role in the liberation of the individual and collective from unconsciousness. The shadow represents the potential of its opposite, that is the development of self-consciousness (Jung in Radin: p. 211). In the trickster myth, we find an assessment of "everything that a man can

never get the better of and never finishes coping with" (Jung in Radin: p. 210).

Native American trickster tales as told by Boasians appear as abstracted texts, readable as literature or myth. They are meant to reflect and go beyond the histories and contexts in which they are collected and interpreted. They contain fragments pieced together of more archaic tales and characters and cultures, and provide clues to the nature of the human mind. The Boasians critique older understandings of Native Americans as either devilish or morally pure by insisting on understanding material, narrative, and symbolic forms in cultural and historical context. But they also make assumptions about the boundedness of cultural groups and make attempts to correct for historical influences to find "true" cultural accounts that will give insight into fundamental human traits by accessing more primitive aspects of life. While the Boasians critique evolutionary ideas of culture, their examinations of trickster tales are shaped by assumptions about an evolutionary hierarchy of cultures that place native peoples closer to archaic humanity.

While Radin and Jung consider the trickster an inverted marker of the structuring principles of psychic and social order, Ellen Basso examines trickster and creation myths of the Kalapalo Indians in Brazil to question the notion of unity of the psyche, the personality, and social order itself. She explores the significance of storytelling as performance in the interpretation of these tales. She focuses on language use in performance to show how Kalapalo ideas of deception are rooted in the contingencies of the lived rather than a cultural unity of myth. Critiquing Radin she explains that the trickster's morality is not what is most significant but rather his immanence, that is "the consequences of the ability of a trickster (or a person) to act inconsistently and experience inconsistencies, in other words, to actively participate in dissolving or scattering the self in order to achieve a new personal understanding, a new identity" (Basso, 1987: p. 7). Taugi is the main male Kalapalo trickster who adapts the environment to make it habitable by people. This creation myth is built upon "a narrative accumulation of the various feelings and powers of different mythic personages who make up the human pedigree. These feelings and powers, passed down from one generation of Dawn People to the next, culminate in the blossoming forth of humanity in all its peculiar, passionate complexity" (Basso, 1987: p. 9). The less common female trickster is Nafigi. The male and female tricksters are according to Basso make a complementary yet opposing pair (Basso, 1987: p. 225). Taugi mocks and resists "signs of relative social competence and power" with which men struggle (Basso, 1987: p. 225). These include concern with wealth, the use of language and sarcasm, the ability to seduce women, insatiable female lust, the achievement of physical perfection, and the scorn of friend and family (Basso, 1987). The female trickster is a "sexually compulsive vampire in her relations with human beings" (Basso, 1987: p. 225). She refracts female concerns with being seen as gossiping and deceptive and as seductive of men. Female tricksters are not usually playful or deceptive but instead reflect the opposite of how women are seen. Most significantly, Basso argues that trickster tales must be understood not in static texts or formal types but rather through language and performance, in "the speech-centered nature of a trickster's activities" (Basso, 1987: p. 229). The trickster is significant as an embodiment of performance and contingency that must be reflected in methods of analysis, whereas conversely, for Boas and Radin, the relevance of the trickster character is contained within myths as detachable, transportable texts. But for both Radin and Basso, the trickster is a form of self-consciousness, a contingent, ambiguous way that a society reflects collective and individual selfhood back at itself.

The trickster plays a small but significant role in Claude Levi-Strauss's development of the structuralist analysis of myth in that the notion of trickster as social mediator becomes a way to argue that myth should be understood through tensions between polar oppositions in signs and categories. Levi-Strauss uses material on North American tricksters as one example in his groundbreaking paper "Structural Study of Myth" (1955). For Levi-Strauss myths hide and distort their true meaning. His structuralism aims to bring order and reveal "some basic logical processes which are at the root of mythical thought" (Levi-Strauss, 1963: p. 224). Whereas Radin examined the narrative structure, character traits, and ordering of myths to find their cultural logic and sense, Levi-Strauss disassembles them, ignoring their surface logics and moralities in search of hidden, deeper realities. Myths are texts that must be broken into constituent parts and reorganized to uncover the more profound grammatical categories not tied to narrative order or proximity in the telling or performance of the myth that will point to their meaning. For him myths are the opposite of poetry. If poetry relies upon language use for meaning and aesthetic sense, myths must be abstracted from language – from any particular enactment – to break them into their significant units and rebundle these parts to get at myths' hidden meanings. Levi-Strauss's concerns with myth, order, and the human mind reimagine the significance of the trickster. The trickster is a mediator caught between uncontrolled consumption and the production of the social world (Carroll, 1981: p. 307). The structuralist logic of the trickster comes as "his mediating function occupies a position halfway between two polar terms, he must retain something of that duality – namely an ambiguous and equivocal character" (Levi-Strauss, 1963: p. 226). Levi-Strauss uses the trickster to demonstrate a fundamental way that signs work in a structuralist system. For Levi-Strauss, the trickster is a mediator between nested pairs of polar oppositions, life and death, agriculture and war, herbivorous and carnivorous animals that become triads. Tricksters are carrion eaters, Ravens and Coyotes, that mediate between herbivores and carnivores. Mediators of primary semiotic oppositions generate oppositions on the next order. Tensions between opposing pairs are played out in mediating signs, which contain that tension and direct it to the next level (Levi-Strauss, 1963: pp. 224–225). Tricksters embody this dialectic. Levi-Strauss's reuse of trickster myths in developing structuralism's logic shows the enduring analytic significance of this category.

African Tricksters, Transgression, and Social Order

As in Native American studies, researchers in Africa in the first half of the twentieth century collected trickster tales as folklore and religious representation. Various African mythic characters have been fit in to the category of trickster – those that blur

social categories, inhabit spaces of moral ambiguity, mediators living at the crossroads of humans and deities. Early Africanist anthropologists seem to have had trouble fitting tricksters into their more systematic research, often collecting stories in separate volumes from their major works of social analysis. Evans-Pritchard's *Azande Trickster* is a collection of stories about Ture the spider, the Azande trickster that follows on his famous *Witchcraft, Oracles, and Magic Among the Azande*. Melville Herskovits collects folklore as part of his more well-known research in Dahomey. R.S. Rattray publishes his collection of Ananse spider trickster tales after his influential studies of Ashanti (Asante) society and religion. Robert Pelton's reworking of classic ethnographic and folkloric materials of Herskovits, Rattray, Marcel Griaule, and various scholars of Yoruba life in *The Trickster in West Africa* has been a major influence on how the trickster figure has been understood. In close readings of trickster tales in relation to West African cultural cosmologies, he argues that the trickster brings social relations into discourse through humor and linguistic and spiritual mediation. Pelton places previously collected tales from a variety of contexts into dialogue to paint a picture of the trickster character. In turn, his textual readings are used by later scholars seeking the trickster's importance. Pelton portrays African cultures as unchanging timeless units and uses the trickster to define what he sees as a shared West African cosmological sensibility.

Whereas Native American analyses focus more on making sense of the moral and cultural logic of tricksters, the study of African tricksters emphasizes their roles in the making and unmaking of social structure through a Durkheimian–Turnerian idea of ritual progression through a liminal phase to symbolic reaggregation and affirmation. They have been taken as embodiments of social mediation, particularly in their control of language, communication, and forms of exchange. Their doubleness and lived contradictions have also been seen as markers of the creative logic of African societies portrayed not only in collected stories but in their contextually specific performances. Scholar of religion, Mircea Eliade, and anthropologist of ritual, Victor Turner, have been influential in shaping understandings of African tricksters as liminal figures, whose symbolic inversions and excesses provide ritual signs of antistructure than in the final instance point to and reproduce normative social values (Douglas, 1970; Babcock-Abrahams, 1975). Ethnographers of African tricksters have paid attention to the poetics of their expression finding meaning in the disjunctures between action and explicit textual intent.

African tricksters also raise questions for Western scholars about morality, who seem perplexed by how characters doing immoral things can be mythic, beloved foundational cultural icons. Rather than resolving contradictions between morality and immorality, tricksters in the process of provoking conflict, lying, being sexually aggressive, stealing, and scheming, in fact, create social relations. African tricksters are manifestations of self-consciousness and social reflexivity. They build the world through producing debt and desire (Vecsey, 1981). Tricksters link "disruptive and recreative possibilities" (Pelton, 1980: p. 128). Conflict and contradiction create sociality, contrary to scholars who worry that the trickster's desires and selfishness are antisocial.

In relation to language, Beidelman points out that for the Kaguru of Tanzania, "Trickery is often expressed through deviant speech patterns. For example, a narrator will portray a hyena's speech as slurred and bumbling, an old woman's as hoarse and grotesque, and a hare's or youngest sibling's as high and lilting. In discerning relations between words and meanings, there are profound ambiguities and difficulties involving misunderstandings and deceit and varying degrees of eloquence and guile" (Beidelman, 1980: p. 31).

Unlike the Winnebago trickster tales, which constitute a cycle, *Anansesem* are an indeterminate set of tales "whose inner principle of order is somehow Ananse himself" (Pelton, 1980: p. 30). Ananse is the spider trickster of the Akan people of Ghana. R.S. Rattray, the first official anthropologist in the Gold Coast colonial service and the preeminent ethnographer of the Asante collected *Anansesem* to accompany his other ethnographic research on religion, politics, and society. Even tales that do not feature Ananse explicitly are included in this genre of folktales. Ananse has human and animal characteristics and the stories he both tells and inhabits shift between mythic time, mundane social settings, and relations with Nyame the Supreme God. He is an eminently social being; his stories revolve around his attempts to dupe those around him into relinquishing wealth, food, sex, and value. This usually involves word play and the complex formulation of tricky plots. While at times he succeeds, usually Ananse is foiled by his own desires and cleverness.

One well-known Ananse story demonstrates his relationship to language, transactions, and social mediation is the tale of Ananse and the pot of wisdom. Its multiple variations that point to the flexibility of the storytelling structure. In one version Ananse aspires to be chief. He has clandestinely collected all of the world's wisdom and carries it in a pot on his head. He looks for a place to hide it so that he alone will have wisdom to outsmart anyone. He ties the pot to his stomach in order to climb a tree and hide it. Because of the awkwardness of the pot, he is unable to climb. If he drops the pot to pull himself up, he will loose all the wisdom but if he does not then he cannot move. Ananse's son finds him stuck in this dilemma and suggests that he place the pot behind him and then climb up to hide it. Having received this advice from his own son, Ananse realizes he does not have all of the wisdom in the world. Ananse, humiliated by being outwitted by his own son, drops the pot, which breaks, spilling the wisdom everywhere. Forevermore, he lives in shame in the tree, which is why spiders live in trees.

In another version that varies Ananse's intents, emotions, and motivations, Ananse begs or tricks God to give him wisdom to share with the world. Ananse is given the wisdom to share with everyone but decides to keep it himself and hide it so no one can get it. As he is climbing the tree with the pot tied around his waist, he gets stuck and his child advises him to remove the pot and climb up. In anger at being embarrassed and outwitted by a young child he smashes the pot and wisdom is scattered everywhere.

Tricksters are highly mobile figures of cultural self-representation and signs of history. By this I mean that rather than remain characters in mythological folkloric tales they are appropriated by various ongoing national, economic, and artistic projects. Indeed in urban cosmopolitan African worlds defined by business people, politicians, and artists, actions and intents are often explicitly debated and discussed as tricksters (Shipley, 2009; Hannerz, 1987). In Kinshasa, as White shows,

the trickster manifest in performances and discourses of popular urban music, shapes a particularly African modernity (White, 1999: p. 158). In Ghana, Ananse and trickster storytelling become the basis of first an eclectic modern variety theater known as concert party theatre and later the National Theatre Movement. Around Ghana's independence from British colonial rule in 1957, Prime Minister Kwame Nkrumah and various playwrights, artists, and scholars identified *Anansesem* as a strong, indigenous cultural tradition that could ground the new nation's attempts to develop modern artistic forms. Efua Sutherland one of the founders of Ghana's National Theatre Movement in the 1950s and 1960s coined a term for a new genre Anansegro, meaning Ananse theater, to adapt the essence of Ananse's cultural wisdom and formal logic for the modern stage (Sutherland, 1975). Her best-known play, "Marriage of Anansewa" tells how Ananse devises a scheme to become wealthy by promising his daughter in marriage to three prominent chiefs. When they all plan to marry her the same day he convinces her to feign her death. This was widely seen as a metaphor for the way that Kwame Nkrumah tried to balance political allegiance and court favor between Cold War powers in the 1950s and 1960s. This play demonstrates how Ananse trickster stories are appropriated by national cultural projects that maintain the importance of this mediating figure and performative forms of indirection and double-voicing long significant in Akan and West African communication and language use (Kwesi Yankah, 1995). The recent boom in film industries in Ghana and Nigeria also appropriate morally ambiguous trickster figures as a key narrative feature. Hip-hop artists and popular musicians have also adopted Ananse tales in their lyrics and poetic forms, with one artist even taking the stage name of Kweku Ananse. Ananse stories while describing particular aspects of Akan sociality have been explicitly appropriated to define a Ghanaian cultural nationhood and transposed to address aspects of modern urban life in Ghana (Shipley, 2009, 2013, 2015).

Ananse is a mythical human-animal-spiritual being, the teller and main character in stories, a humorous hustler; but other West African tricksters like Legba of the Fon and Eshu of the Yoruba are more firmly tied to divinity. Legba, like Ananse, is a master of language, a mediator of social relations. Shrines to him are prominent at the entrance to houses and villages in Dahomey. He is the youngest child of Mawu-Lisa, the supreme being of the Fon of Benin. Legba mediates between their mother Mawu, the female aspect of the divinity, and the various realms ruled by his older siblings. Pelton quotes Herskovits: "Legba knows all the languages known to his brothers, and he knows the language Mawu speaks, too. Legba is Mawu's linguist. If one of the brothers wishes to speak, he must give the message to Legba, for none knows any longer how to address himself to Mawu-Lisa. That is why Legba is everywhere" (Pelton, 1980: p. 73). He is also the patron of divination. Fa is his master though Legba must speak for Fa. Legba is key to "Fon self-understanding" through initiation rituals and through "the special language that is their divination" (Pelton, 1980: p. 112). Legba lives among people, though his transgressions and access to power make him dangerous to bring into the house. Legba is a sign of male potency, and Legba masquerades dance as part of initiation rituals. "Legba's sexuality is the great symbol of his transforming power, not because…of legitimizing promiscuity, but because it forces responses that reveal possibilities hidden with the existent world" (Pelton, 1980: p. 88). But he is a creator and facilitator not a producer, a mediator who has access to power rather than producing power (Pelton, 1980). Legba is present when there is social risk in the market, in relation to raising children, in royal and political administration where he both causes and neutralizes problems; he is there "to rechannel far more than to neutralize, the various forces present in such situations" (Pelton, 1980: p. 83).

Legba, like the other West African tricksters, Pelton examines, "lives where separate worlds meet and can move back and forth between them" (Pelton, 1980: p. 88). Legba is closely related to the Yoruba Eshu. In the Yoruba pantheon of orisha deities, Eshu (Esu, Elegba, Elegbara) is the trickster, a linguist and a mediator between the human world and the gods. Eshu is also present in markets and at crossroads, places of transition, translation, and mediation. Eshu, like Ananse and Legba, is a troublemaker the "embodiment of paradoxes" (Pelton, 1980: p. 129). "When men are quarrelling Elegba is said to be present; when a man has done wrong he is asked if Elegba prompted him" (Wescott, 1962: p. 337). He is an "agent provocateur," "a messenger of the gods," and "a homeless wandering spirit," who inhabits "the market-place, the crossroads, and thresholds of houses" (Wescott, 1962: p. 337). Eshu is also key to Yoruba divination; he "receives a portion of every sacrifice commanded through divination" and "makes his 'presence and power' known each time a diviner holds a session" (Pemberton in Pelton, 1980: p. 129). Eshu is actively present in Yoruba life through sacrifice and divination.

Ananse is a playful schemer, Legba is forgiving and mischievous, and Eshu is vengeful and bold (Pelton, 1980: p. 130). All have huge appetites for sex and valuable things and activities. They desire to be at the center of social action, provoking conflict and producing excitement. While Ananse is motivated by his self-interest or sometimes the pleasure of trickery, Eshu and Legba at times seem to go out of their way to cause trouble for the sake of it. One well-known story with many iterations tells of how Eshu creates conflict between two friends who own farms next door to each other. Eshu wears a multicolored cap and holds his pipe in front of him at his neck and his staff behind him and walks the boundary between the farms. The friends fight about what color his hat was and which way he was going (Frobenius, 1968; Bascom, 1969; Pelton, 1980). Here, Eshu's power comes from the ability to fracture the idea of a single truth into multiple perspectives. Scholarship on these West African tricksters has focused on them as powerful, transgressive, and ambivalent figures, who represent cultural, cosmological logics.

Trickster as Response to Inequality

Studies of tricksters as mythological figures in so-called traditional societies and debates about structuralism, functionalism, archetypes, and neo-Durkheimian religious affirmations ebbed in the early 1980s. Though over the next decade, a new trickster popped up in a number of studies in which older research is reworked to make arguments about power and the global, comparative relevance of the character.

Some of these studies use the trickster to authorize the return to older comparative religions and folkloric projects from the early twentieth century. Others reimagined the trickster in a fundamentally different way than older studies. Rather than providing insight into a culture's cosmology or the psychic unity of the human mind, the trickster became a historical figure, a sign of agency for oppressed social groups and subcultures. Here the trickster is a multivocal character who navigates hostile terrains, speaking back to power, opening up subtle modes of communication and agency for the powerless. Scholars interested in this version of the trickster have focused on the trickster's ability to mediate between realms, to hustle, to aspire, to survive, and to address complex social situations through humor. In the 1980s and early 1990s, trickster scholarship delineated, in effect, a theory of resistance. Reexamining Native American and African tricksters and their contemporary manifestations in Native American literature and culture, African postcolonial worlds, and African diasporic narratives and religion in North America, Haiti, Brazil, Cuba, and beyond scholars have identified a fundamental duality and double-voicing that provides a form of cultural resistance and expression for peoples living under conditions of inequality.

In his 1988 book *Signifying Monkey*: *A Theory of African-American Literary Criticism* literary critic Henry Louis Gates argues Signifyin(g) is the preeminent trope of African-American language use and can be a metaphor for organizing black literary criticism. He focuses on Esu [Eshu] as a key figure of social destruction/production and linguistic mediation in Yoruba cosmology and divination, a trickster who comes with African peoples to the New World through the slave trade and is present in African disaporic religions and ways of thinking. Gates focuses on the "uncertainty or indeterminacy" (Gates, 1988: p. 32), duality, "double-voiced" aspects (Gates, 1988: p. 7), and "meta-linguistic" principles (Gates, 1988: p. 35) of West African trickster discourse manifest in the figure of Esu. As divination is a form of sacred interpretation, translation, and transformation, Esu transports and translates these practices as Pan-African modes of thinking, speaking, and being (Gates, 1988: p. 9). Gates argues that Esu is the patron of literary criticism. "His passage from Africa to the New World and his continued simultaneous existence in the Yoruba-derived cultures of Nigeria, Benin, Cuba, Haiti, Brazil, and the United States allows us to draw upon this compelling black figure as the trope of critical activity as a whole. Whereas Ogun, god of war and the artisan, stands as the writer's muse, it is Esu who stands as the muse of the critic. He can serve us as such because he is both the divine linguist and the divine interpreter, the controlling principle of its representation and its interpretation" (Gates, 1988: p. 35). Gates is interested in "Esu's double-voiced representation in art" (Gates, 1988: p. 51) and the specific historical connections between West Africa and Yoruba practice and black diasporic expression. He compares Esu to African-American forms of Signifyin(g) and double-voicing. Esu becomes a literal and metaphoric way for Gates to talk about black linguistic practices and modes of critical thought. Tricksters and those living under conditions of oppression speak in double-voiced ways such that they say two things at once; the explicit meaning of a statement covers and refracts an indirect, deeper meaning. Pelton and Gates both point to the importance of African tricksters' humor and double voicing as modes of engaging profound philosophical issues for African and African diasporic peoples. Whereas for scholars of African expression, indirection represents a fundamental aspect of West African cosmology, for Gates and scholars of resistance, this is a practice that is developed as African diasporic peoples and other oppressed groups live with intense inequality and violence.

James C. Scott's work which since the 1980s has shaped understandings of resistance in relation to culture and politics, is built upon a metaphoric trickster. His argument in the influential *Domination and the Arts of Resistance* points to African-American trickster tales as strategies of resistance for people living in an oppressive society that determines modes of narrative and spatial relations. He argues "there is a third realm of subordinate group politics" strategically situated between the self-image of elites and the "hidden transcripts" of the oppressed that are voiced in safe private spaces where they can speak about anger or revenge (Scott, 1990: pp. 18–19). The arts of resistance, however, demarcate "a politics of disguise and anonymity that take place in public view but is designed to have a double meaning or to shield the identity of the actors. Rumor, gossip, folktales, jokes, songs, rituals, codes, and euphemisms – a good part of the folk culture of subordinate groups – fit this description. As a case in point, consider the Brer Rabbit stories of slaves, and trickster stories more generally. At one level these are nothing but innocent stories about animals; at another level they appear to celebrate the cunning wiles and vengeful spirit of the weak as they triumph over the strong" (Scott, 1990: pp. 18–19). Here folklore and folk characters give insight into politics and power rather than standing as timeless cultural myths.

While early ethnographers tried to morally reconcile the trickery, humor, and selfishness or tricksters with their heroic and productive capacities, for Scott the trickster's two-sidedness reflects cultural reactions to social inequality. For Scott culture makes sense primarily in relation to struggle. "Nothing illustrates the veiled cultural resistance of subordinate groups better than what have been terms trickster tales … Typically the trickster makes his successful way through a treacherous environment of enemies out to defeat him – or eat him – not by his strength but by his wit and cunning." Trickster escapes by "knowing the habits of his enemies, by deceiving them … the structural position of the trickster hero and the *strategemx* he deploys bear a marked resemblance to the existential dilemma of subordinate groups" (Scott, 1990: pp. 162–163).

Gates and Scott point to the trickster in culture and society, as a figure navigating internal power dynamics shaped by historically structured, unequal relations among cultural groups. Here trickster myths do not stand for fundamental cosmologies or cultural worldviews but reflect struggle and how people without direct access to power use indirect means to claim agency in the midst of violent conditions that continue to hold them down.

In recent years, scholars and popular writers have built on James, Gates, and others to emphasize the potential of the trickster as a general metaphor and social type, in some ways returning to older ideas of archetype. Popular and folkloric writers such as Hyde and Scheub take the trickster around the

globe as a way to think about universal humanity and narratives of creativity. Studies such as these bring together a diverse set of European, African, Native American, and Asian tricksters from older ethnographic and folkloric texts, fiction, politics, and the arts. Scheub takes the trickster character found in oral literature and mythology around the world. He focuses on the temporality of narrative, arguing the trickster stands for a moment of transformation. In this comparative argument heroes are always a bit of the trickster. He provides an impressive, several page list of tricksters from all over the world. For Scheub "Tricksters are the timeless energy, the eternally liminal, the ordering and the chaotic … They are primordial, now sublime and now debased…. We see ourselves in the trickster…. Whenever there is chaos and order, the trickster is there. And for a time, the hero is a trickster, the tale character is a trickster, God plays the role of trickster" (Scheub, 2012: p. 12). Here moments of creative possibility and of heroic (salvation) are always tied to their potential inversions. He argues the trickster is the "fundamental building block of storytelling" that contains with it the "seed of transformation" key to all stories (Scheub, 2012: p. 24). For Hyde, the trickster is also a global figure that points to creativity in the face of uncertainty. Tricksters are travelers and inventors. Structurally, his argument relies on trickster as universal archetype, if in a more functional one than the Jungian version. He finds tricksters everywhere, as writers, painters, political figures, across time and space; at times the category is literal at other times metaphoric. For Hyde the trickster is a romanticized marker of hope, representing a mode of expression and a form of mobility and inversion defined by the potentials of the individual in the face of power. He is not concerned with whether or not the figures he identifies as tricksters have been seen as such in the contexts of their relevance but in arguing for universal idea of human creativity.

Reappropriating Tricksters

While Paul Radin's work on the Winnebago trickster focused on rich explication of a specific trickster cycle and making sense of him in cultural context, his work was influential on a later generations of scholars searching for irreverence and power. The opening paragraph of the preface to the 1956 edition of *The Trickster* anticipates the ways that scholars will elaborate upon this character as a universal archetype:

> Few myths have so wide a distribution as the one, known by the name of *The Trickster*, which we are presenting here. For few can we so confidently assert that they belong to the oldest expressions of mankind. Few other myths have persisted with their fundamental content unchanged. The Trickster myth is found in clearly recognizable form among the simplest aboriginal tribes and among the complex. We encounter it among the ancient Greeks, the Chinese, the Japanese, and in the Semitic world. Many of the Trickster's traits were perpetuated in the figure of the mediaeval jester, and have survived right up to the present day in the Punch-and-Judy plays and in the clown. Although repeatedly combined with other myths and frequently drastically reorganized and reinterpreted, its basic plot seems always to have succeeded in reasserting itself.
>
> Radin, 1972: p. xxiii

Considering his mentor Boas's careful focus on detail and reticence to make generalizations, and his criticism of Radin for rushing to make assertions, it makes sense that this statement comes after Boas's death. Radin seems freed to highlight the social power of transgression, arguing that trickster's inversions can function as satires to voice protest "against the many, often onerous, obligations connected with the Winnebago social order and their religion and ritual" (Radin, 1956: p. 152). In adopting the trickster as a mediator of culture and power that bridges lived worlds and analysis, Scott and scholars of resistance and Hyde and scholars of creativity have lost the specificity of social and historical conditions of inequality, reducing culture, difference, and complex forms of subjectivity to a seductive, preexisting analytic category.

Trickster characters have been good to think with and reveal various scholarly trends in how writing about them has changed over the course of the last century. They show an ongoing scholarly fascination with the seeming contradictions between uncontrolled desire/transgression and social totality, deviance and psychic unity. Scholars seem anxious to reconcile appetites for sex, food, and conquest with logic, rational thought, social good, and totality.

Scholarly accounts of tricksters abound and seem to get more romanticized over time. Analysts of myth and literature find in trickster stories ways to explain profound philosophical and psychological conundrums around human creativity, ambivalence, altruism, chaos, and desire. When the category dissolves into a discomforting mess of particularity, its elements resurface elsewhere. But there are certainly a set of tales and characters from around the world that show an uncanny resemblance to each other when taken from abstracted texts. Trickster tales are sometimes origin stories, tales of the creation of the social order. They can resemble tales of saviors. They can also be tales of chaos and subversion. Tricksters are fundamentally dual in a number of ways and embody and play out various social contradictions. They live in ambiguous temporal-spatial planes and shift between worlds rapidly in mid story. Their tales do not always go in chronological order or follow simple narrative progressions. Their stories often move between mythic time and lived worlds. They inhabit hybrid and changing bodies. They are animals, human-animals, and human-animal-supernatural beings. They are greedy, arrogant, liars, selfish, destructive, devious. They are productive, improvisational, unpredictable creators of culture, heroes and antiheroes.

The trickster's omnipresence and numerous reinventions seem indicative of the continuing need in ethnographic, religious, and literary inquiry to find coherence and commonality especially in the face of contradictions. The category of trickster has been a way that anthropologists have theorized the relationships between individual morality and agency and social organization and power, in the process rethinking how ideas of culture relate to historical and mythic frameworks.

Abstract

Much of the Western world is experiencing a 'a crisis in public confidence in government.' Levels of political trust – are declining. In the mid-1970s, social, political, and economic turbulence throughout the developed world led to worries that governments had lost their legitimacy. The Organization for Economic Cooperation and Development (OECD), representing 33 largely developed countries, warned, "Citizens across the OECD have lost their confidence in the ability of policy makers to solve economic problems and respond to their needs and demands." What is trust in government? How do we measure it? What are the roots, dimensions, and consequences of this malaise? This article surveys the literature on the meaning and measurement of political trust and then inquires into the causes and consequences of this declining confidence in our institutions for the health of democratic societies.

In much of the Western world, we hear of a crisis in public confidence in government. In the mid-1970s the social and economic turbulence throughout the developed world led to worries that governments had lost their legitimacy and that there was a crisis of confidence in government (Crozier et al., 1975). Since the 1980s, we have heard of a 'confidence gap' in public and private institutions, 'disaffected democracies,' and 'democratic deficits' (Lipset and Schneider, 1983; Pharr and Putnam, 2000; Norris, 2011). The Organization for Economic Cooperation and Development (OECD), representing 33 largely developed countries, warned, "Citizens across the OECD have lost their confidence in the ability of policy makers to solve economic problems and respond to their needs and demands" (OECD, 2013).

What is trust in government? How do we measure it and what are the roots of this malaise? I survey the literature on both measurement and causes and then ask what the consequences of this declining confidence in our institutions are.

There are controversies surrounding each of these issues, including (perhaps starting with) measurement. I consider each in turn.

What Is Trust in Government and How Do We Measure It?

Trust in government is the expectation that the state will provide basic services and keep the country secure and prosperous, an evaluation of government performance. Hetherington (2005: 9) defines political trust "as the degree to which people perceive that government is producing outcomes consistent with their expectations…."

Hetherington implies that trust in government varies over time and that the primary factor shaping political trust is the state of the economy. Hetherington (2005: 9, 10) cautions against a one-to-one correspondence of economic conditions with political trust. Perceptions, not economic statistics, matter for trust in government. People are more likely to evaluate government negatively during periods of financial distress. The 'confidence gap' argument was developed in response to the economic turbulence of the 1970s. The contemporary decline in trust across developed nations reflects "citizens' growing expectations [that] have been hard to address with limited government resources…. The financial and economic crisis that started in 2008 led to a significant loss of trust in government," (OECD, 2013:10, 20).

How do we measure political trust? There are two standard survey questions in the literature. First is the question with the longest history:

> How much of the time do trust the government in [the national capital] to do what is right?

This question has been asked in the United States – in the American National Election Studies – since 1958.

An alternative question, used in the World Values Survey (1981–2008), the United States General Social Survey (1972–2012), and the Gallup World Poll (2011–2012) is (using the Gallup question wording, see OECD, 2013: 25):

> In this country, do you have confidence in each of the following, or not? How about national government?

The confidence and trust measures are close, if not identical. The 1987 General Social Survey in the United States included questions on trusting the federal government and confidence in the executive branch (the Presidency), the legislative branch, the Supreme Court, and the army. I created an index by factor analysis, which was correlated with trust in the federal government at 0.47 – hardly perfect but fairly strong for survey data.

Third – a variation on the trust in government question – is trust in specific institutions. Hetherington (2005: 11) cautions against confounding trust in specific institutions – or the people holding them – with trust in government. Attitudes toward governmental and nongovernmental institutions cluster together, so one can construct a more general index of trust in government. Uslaner (2014a) finds a single dimension

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93151-9

for trust in the Prime Minister, the parliament, the courts, the police, and the military using data from the Afrobarometer, the Arab Barometer, and the Global Barometer for Asia and Latin America.

Finally, for many years the American National Election Study (ANES) included an index of trust in government. In addition to the question "How much of the time do you trust the government in Washington to do what is right?," the trust scale included: "Do you think that quite a few of the people running the government are crooked, not very many are, or do you think hardly any of them are crooked?" The index also included the question: "Would you say the government is pretty much run by a few big interests looking out for themselves or that it is run for the benefit of all the people?"

Most discussions of trust in government in the United States (cf Miller, 1974; Citrin, 1974) use the simple trust question rather than the index. It is unclear whether the scale is measuring a common notion of faith in institutions or a causal chain from being crooked or looking out for yourself on mistrust. In less than half of the years all measures were included, the three measures formed an acceptable scale (alpha > 0.6 in 10 of 21 years). Only once since 1988 did the alpha exceed 0.6; the 'officials crooked' variable was weakly related to the other two. Question wording is a central issue. But so is measurement. First, what is the scale employed? The standard question based upon the ANES has a fourfold response scale ('almost always,' 'most of the time,' 'some of the time,' 'hardly ever'). In the late 1990s, the Swiss Household Panel and the Citizenship, Involvement, Democracy (CID) cross-national surveys in Europe (For the Swiss Household Panel, see http://www.swisspanel.ch/. For the history of the CID project, see http://www.mzes.uni-mannheim.de/projekte/cid/and http://www.mzes.uni-mannheim.de/projekte/cid/background.htm. See Van Deth et al. (2007) for essays based upon the public surveys.) shifted to an 11-point scale. The European Social Survey (ESS) followed suit. (See http://www.europeansocialsurvey.org/.)

The 11-point scale was seen as a methodological advance by the Swiss Household Panel and the CID and ESS surveys. Scherpenzeel (n.d.: 1) argued:

> Scales with relatively few response alternatives force respondents to categorize their reaction towards an attitude object instead of directly mapping it onto the response continuum, thus causing information loss…respondents differentiate more between objects when offered response scales with greater numbers of categories…

Scherpenzeel (n.d.) argues that the 11-point scale demonstrated the greatest reliability and validity of any measure of satisfaction in a survey across 10 nations. Zmerli and Newton (2008) argue that the expanded scale is a better measure. Uslaner (2013a) challenges this claim, arguing that there is a widespread tendency of respondents to choose 'middle' categories (4, 5, 6) even when they give more extreme answers to the measures with fewer categories. These 'middle' responses, which Uslaner calls 'clumping,' do not discriminate well among attitudes – a score of 4 is not significantly different across political institutions than is one of 6.

The Determinants of Trust in Government

What factors shape trust in government?

Satisfaction with the Direction of the Country and the Economy

Hetherington's definition points to the role of 'national conditions' – especially the state of the economy – to be the prime mover of trust. Confidence in political institutions, Citrin argued (1974), depends upon the perceptions of leaders' competence. When they get the job done, they are rewarded with the favor of the public. Getting the job done means keeping the economy strong (Listhaug and Wiberg, 1995; Pew Research Center for The People and The Press, 2010: 19).

In 1980, Republican Presidential nominee Ronald Reagan asked voters: "Are you better off now than you were four years ago?" His argument struck a chord – but it was the wrong question. People don't blame political leaders for their personal misfortunes. What matters is how well they have managed the national economy (Kinder and Kiewiet, 1979).

There is a strong relationship between trust in government and satisfaction with the state of the nation in data from the United States (see **Figure 1**). Cross-nationally the results seem weaker. The OECD report (2013: 25) finds less support for an economic link: "…trust in government may not respond to long-term economic developments or absolute standards of living as much as it does to cultural factors, evolving expectations and political developments." Trust in government is lower where people appear to have greater expectations from government, even if they are not the richest. The economic crisis of 2008 seems to have been responsible for lower trust in government across many countries – from the United States (Uslaner, 2014b) to Greece, Ireland, Latvia, Lithuania, Romania, and Spain (Charron et al., 2013: 8).

Figure 1 Trends in trust in government: Pew Research Center for the people and the press. Source: http://people-press.org/2010/04/18/distrust-discontent-anger-and-partisan-rancor/.

Data from the Gallup World Poll for 2012 (see Figure 2) support, though not unequivocally, the link between economic optimism and trust in government. The greatest declines in confidence occur among countries that have been most negatively affected by the 2008 economic crisis (notably Ireland, Greece, Slovenia, Portugal, and Spain). Where the crisis was least felt – in China, Switzerland, and Israel – faith in the state moved upward. These data suggest that the economy is a major factor in shaping confidence in government. But it is likely that perceptions of the economy – and especially views about the future – matter more than objective economic statistics.

Figure 2 Changes in trust in government (Gallup). Source: Gallup World Poll and OECD. http://www.pewresearch.org/fact-tank/2013/11/21/confidence-in-government-falls-in-much-of-the-developed-world/ (accessed 01.12.13.).

What Government Does?

Government performance is more than just economic outcomes. It is also how governments provide basic services, especially when are dealing with natural disasters.

Outside the developed world, governments may not always provide basic services – water, electricity, telephone – efficiently. When service delivery is intermittent, people blame the government and have less faith in it (Uslaner, 2011a, 2014a). The quality of public service in developed countries also shapes trust in government: Better treatment from public employees leads to more trust in government (Christensen and Laegreid, 2002).

Public confidence in government rises and falls with perceptions of how well the state deals with major disasters. In the United States, the perceived poor response to Hurricane Katrina in Louisiana and Mississippi in 2005 led to less trust in government, particularly among people living in the affected areas (Nicholls and Picou, 2013; Uslaner, 2011a). The perceived inadequate response of both the government and the nuclear energy company Tepco to the Japanese tsunami in 2011 led to sharp declines in trust in both government and private institutions (Foster, 2011; Uslaner, 2011b). When people are most in need of government assistance – and believe that they have not received it – they lose faith in the state. This is especially the case, as in the Japanese tsunami, if people believe that public officials have conspired with the private sector to hide information that could have spared lives.

Corruption

People have less confidence in governments they believe to be corrupt. This seems to be almost tautological, since the ANES index of trust in government included the question of how many officials are crooked. While there is support for this thesis, it is not universal. Uslaner (2011a, 2014a) reports strong support for this argument in transition countries and most of the developing world. Corruption leads to less trust in both government and other people when it is perceived to be linked to inequality. When government officials get rich at the expense of ordinary people, citizens see the political system as unfair. The institutions that are supposed to be the *least* biased in a well-functioning state, the courts and the police, will be perceived as *the most corrupt* (Rothstein, 2000; Uslaner, 2008: Chapters 5 and 8). Petty corruption – small payments to public officials, police officers, teachers, doctors, among others – do not enrich the recipients. So petty corruption does not lead to less trust either in government or other people (Uslaner, 2008: Chapters 5 and 8).

People object to corruption because they see officials (and business people) getting rich at the expense of the state. But as political leaders get rich, corruption is a tax on the poor. There is less money in the public purse for social expenditures such as building schools and hospitals. And often people have to pay bribes to get these services. Corruption makes leaders rich and leads to less effective service delivery and lower economic growth, again taxing the poor (Mauro, 1997).

Does good economic performance mitigate the effects of perceived corruption on trust? Chang and Chu (2006) find no support for this argument in samples from five East Asian

nations. Perceptions of higher corruption lead to less trust in government even when people see strong economic performance, are satisfied with democracy, and expect the future to be bright.

There may be some indirect evidence that strong economic performance might matter when corruption is high and democratic governance is weak. Klasnja and Tucker (2013) report experimental results comparing voters in Sweden and Moldova. When confronted with arguments revealing dishonest politicians in the country with low corruption (Sweden), respondents said that they would vote against these political leaders *regardless of their perception of economic conditions*. In high-corruption Moldova, with less of a history of democratic governance, respondents indicate opposition to dishonest incumbents only if the economy was perceived to be weak. Voting is not the same as trust in government, but this result might well be generalizable.

Winners and Losers

People are more likely to trust the government if they have supported it in the past. If you vote for the party in government, you are more likely to trust it. Anderson et al. (2005: Chapter 5) provide mixed support for this hypothesis across countries. However, the effects are particularly powerful for strong party identifiers for the more ideological extreme voters.

In the United States there have been only modest correlations between partisanship and trust in government. As the parties have become more polarized, the link has strengthened (Hetherington, 2008: 21; King, 1997).

McCarty et al. (2006) show strong linkages between growing income inequality in the United States and partisan polarization. Uslaner (2013b: 1, 7) shows that rising inequality accounts for approximately a third of the long-term decline in trust in government in the United States. Fifty eight percent of Americans trusted their government in 1958 compared to 22% in 2010 (Uslaner, 2013b: 15). In contemporary American politics, the rise of the Tea Party as a movement largely within the Republican party, shows the impact of polarization. The Tea Party, founded as a protest against big government, is founded on mistrust of the state.

In the 2010 ANES Evaluations of Government and Society Study (wave 1), 95% of respondents who said that they support the Tea Party did not trust government–compared to 61% who oppose the Tea Party (and 78% who neither supported nor opposed the movement). Almost 60% of strong Republican identifiers support the Tea Party compared to just 4% of Democrats. Trust in government is becoming increasingly partisan.

An explanation based upon polarization has limited applicability. Polarization is primarily an American development. Many of the mainstream parties in Europe have converged *toward* each other (on Britain, see Adams et al., 2012). Yet in most European countries, right-wing parties based upon opposition to immigration have gathered support.

Rydgren (2007: 253, 254) argues that the "convergence [of mainstream parties] may result in a feeling that the established parties 'are all the same.' This, in turn, may fuel popular distrust and discontent in politicians and political parties and create an audience receptive to parties ready to mobilize protest votes." The rise of right-wing populist parties is not the same as the rise of the Tea Party in the United States – but both the supporters of each fear that immigrants (and minorities more generally) constitute a threat to the dominant (white) culture (Jacobson, 2011; Lucassen and Lubbers, 2012), In both Europe and the United States, the rise of right-wing groups is based upon a loss of faith in the mainstream parties and in the government more generally.

Incivility and Gridlock

Otto von Bismark, Chancellor of Germany in the late nineteenth century, said, "Laws are like sausages, it is better not to see them being made." (See http://www.brainyquote.com/quotes/quotes/o/ottovonbis161318.html (accessed 31.12.13.).) Hibbing and Theiss-Morse (1995) find that Americans don't like Congress because they find the bickering and incivility of the legislative process to be unseemly: The legislative process is not pretty. This leads to less trust in the legislative branch and almost certainly to government in general (although they do not test this).

More recently the decline in trust in government has been linked to gridlock – the inability of Congress to agree to legislation. (The term 'gridlock' comes from a description of traffic patterns in which cars are stalled and intersections are blocked. Political gridlock is the 'logjam' of legislation.) Since 2011 the Republicans have controlled the House of Representatives and the Democrats, the Senate, and the two chambers have been unable to reach compromises on legislation. The ideological divide between the two parties is so wide that there is literally no common ground between them (Resnick et al., 2013). This division led to a shutdown of the federal government for more than 2 weeks in 2013 and to the fewest bills passed in the history of Congress (Sullivan, 2013). Trust in government fell sharply and pollster Andrew Kohut attributed this decline to legislative gridlock. (See http://www.pbs.org/newshour/bb/politics/jan-june13/pew_01-31.html (accessed 31.12.13.).)

Gridlock and the open conflicts (and name calling) within Congress (cf Uslaner, 1993) are certainly responsible for declining trust in government in the United States. Elsewhere polarization is not the norm. Jeering and insults are regular parts of legislative life in many parliamentary systems, although the members do not take their distaste for each other outside the chamber as they do in the United States. And gridlock is a decidedly an American phenomenon. Without rules permitting obstruction, as we find especially in the United States Senate, and without divided party control of the legislative and executive branches, minorities are powerless to stop the flow of legislation. So while this explanation undoubtedly explains part of (maybe even much of) the decline in trust in government in the United States, it cannot account for low confidence in the state elsewhere.

Social Trust

Political trust, some say, is part of a larger syndrome of an upbeat world view. Lane (1959: 164) argues, "Trust in elected officials is seen to be only a more specific instance of trust in

mankind." Advocates of a link between the two types of trust maintain that strong government performance makes people feel better about the government and ultimately more willing to cooperate with each other (Brehm and Rahn, 1997: 1008; Misztal, 1996: 198). Citizens rest easier when dealing with strangers if they know that government will enforce contracts. Rahn et al. (1997: 24) argue that when people trust their government, they are more likely to believe that they can influence it. This growing sense of efficacy makes people more likely to trust each other.

Zmerli and Newton (2008: 707) find strong relationships between the two types of trust, arguing that "…according to social capital theory social and political trust are closely associated and mutually supportive….The theory has prima facie plausibility and, as a basic proposition of political sociology that tries to link the social with the political, a great deal of potential theoretical power." Yet, they admit that the "the claim…has poor empirical support."

They are correct. At the aggregate level, the two forms of trust are highly correlated: from 1964 to 2010, the r^2 between the two trust measures is 0.56 in the United States. Yet, Uslaner (2002: Chapter 5) shows that the foundations of political and social trust are distinct. Evaluations of the state of the economy and of specific political leaders shape only political trust, not social trust. Longer-term measures of optimism only determine social trust.

The individual-level correlations are small for both trust in government and confidence (Uslaner, 2002: 150–153). As Hetherington (2005: 9) also argues, this argument "…conflates two very different concepts….In American life, one can easily identify people who trust other people but do not trust government, and with a little more difficulty, one can also identify the reverse."

It is not quite so problematic as Hetherington claims. Trust in government goes up and down with the state of the economy: It rose sharply when the economy recovered from recessions in the transitions from Jimmy Carter to Ronald Reagan and from George H.W. Bush to Bill Clinton. It rose again when the country faced a common threat after the 9/11 attacks. But social trust remained low (except for a brief period right after the terrorist attacks). Trust in government responds to the economics and politics of the moment, trust in people to the long-term optimism rather than to today's economic report (Uslaner, 2002: 153–158).

Why, then, do Zmerli and Newton, among others, find stronger relationships between the two types of trust than do others? Is it context? Uslaner primarily examines data from the United States, but this is not the answer, because Mishler and Rose (2005) use data from Russia and Kaase (1999: 13) focuses on Europe and concludes that the correlation between the two types of trust 'is small indeed.' The principal difference between the analyses of Uslaner, on the one hand, and Zmerli and Newton, on the other, is the measurement of trust. They use the ESS and the United States Citizenship Involvement Democracy survey. (See http://www.uscidsurvey.org/ (accessed 31.12.13.).) Both use the 11-point trust scales while previous studies employed the dichotomous social trust measure and the 4-point trust in government measure. They claim that these scales are "more reliable measures of attitudes and values" (Zmerli and Newton, 2008: 714). The correlations using the 11-point measures are uniformly stronger across European nations and the United States than are those for dichotomized measures (constructed from the 11-point scales) and Zmerli and Newton (2008: 715–717) take this as evidence in support of the new measures.

It is unclear that the higher correlations for measures based upon 11-point scales are superior to those based on dichotomies or four-point scales. The 11-point scales are problematic (Uslaner, 2013a). Romanians were given both the dichotomous and 11-point social trust questions in the CID: The r^2 between them is a mere 0.164. Seventy-six percent of Romanians scoring 4 on the 11-point measure are mistrusters on the dichotomous measure, as are 69% directly in the middle at 5, and even 58% who scored a 6 on the expanded measure.

Uslaner (2002: 68–74) showed that American respondents to a 'think aloud' experiment about trust understood the question and also that responses are quite stable over time. More complex measures have not fared so well (Uslaner, 2014c) over time or as predictors of outcomes that he demonstrated in earlier work (Uslaner, 2002: Chapter 7). The 11-point scale may be artificially leading us to expect that social and political trust stem from common roots, when plenty of evidence suggests otherwise.

Why Care About Trust in Government?

Do we want trust in government? Both the OECD report and Hetherington suggest that trust is a tool to adopt progressive social policies. Hetherington (2005) argues that trust is necessary to gather support for the government to enact policies (at least in the United States) that are redistributive – welfare, foreign aid, assistance to blacks. People who trust government are not always liberal, but they do have faith that government officials will handle their money responsibly. There is thus a link from trust in government to both liberalism and to outcomes that are generally seen as liberal (Hetherington, 2005: Chapter 3). Even people who are not liberal would be more likely to support health care reform if they trusted government – especially to spend their money responsibly (Hetherington, 2005: Chapter 3). Conservatives distrust government, all government and not just Washington (Uslaner, 2001). But when they trust government, they are more likely to support federal programs that provide aid to those who are less fortunate.

The OECD (2013: 22) report makes similar arguments: "people are prepared to sacrifice some immediate benefits if they have positive expectations of the longer-term outcome of public policies, either at a personal level (pensions) or by contributing to the common good (redistribution of income through taxation)."

Trust in government matters when we need the state the most – when the private sector has neither the means nor the will to tackle major social problems. In the second decade of the twenty-first century, trust in government seems in short supply in the West as new issues come to the fore of the political landscape even as – or perhaps especially as satisfaction with economic performance – the key driver of faith in the state has fallen.

Abstract

Trust is at issue when someone makes oneself vulnerable to another who can harm if the trust is misplaced. The recipient of trust is either trustworthy or not, and much of the literature revolves around the evaluation of the trustworthiness of the trusted by the trustor. Trust can exist among those who know each other intimately (personal trust) and among strangers (interpersonal, social, or generalized trust). Trust can have as its object other people or institutions and organizations. In conceptualizing trust to undertake empirical research, two crucial distinctions exist: cognitive vs noncognitive trust and personalized vs generalized trust. The more instrumental and cognitive theorists tend to treat trust as an estimate of the trustworthiness of those with whom one has relationships as individuals or within social networks. In contrast are those who claim trust is dispositional or moralistic. While each tradition treats the work trust does as an empirical question, their conceptualizations are sufficiently distinct so that both their presumptions of the role that trust plays in society and their findings are often incompatible. This leads to debate about the sources of trust and whether trust is essential for good government, economic growth, and harmony.

Trust and trustworthiness are distinct but so implicated with each other that it is generally necessary to consider the second in contemplating the first. Indeed, much of the literature revolves around how to establish and assess the trustworthiness of persons, organizations, and institutions.

The Term 'Trust'

There are several distinct literature on trust and several ways to categorize them. One typology differentiates trust among those who know each other intimately (personal trust) from trust among strangers or relative strangers (interpersonal, social, or generalized trust), which in turn is distinct from trust of government, firms, and other institutions and organizations. Another involves the distinction between trust as a relationship and trust as a disposition or value. There are approaches to trust that rely on rational choice, others that call upon structural functionalism, and yet others that evoke social identity theory. There are surveys of trust, experiments on trust, and formal models of trust.

The concept of trust has a long intellectual history. In political philosophy, Thomas Hobbes argued that trust makes cooperation possible, but that betrayals of trust make it hard to rely upon. John Locke emphasized the importance of mutual trust between the governors and the governed within legitimate polities (Dunn, 1990). In sociology, it is a concept used by scholars as various as Talcott Parsons, Peter Blau, Harold Garfinkel, Niklas Luhmann, and Bernard Barber in their efforts to understand the construction of social order, cooperation, institutions, and organizations, and even everyday interactions. To the economist Arrow (1974), 'Trust is an important lubricant of a social system' because it can enhance efficiency. Confidence, reliance, and assurance are related concepts that some scholars conflate and others distinguish albeit in a variety of ways.

What ties various perspectives together is the recognition of trust as a means to cope with uncertainty, but disagreement remains about how trust comes about, when it should be relied upon, and what kinds of interactions it enhances (see, e.g., Gambetta, 1988; Levi and Stoker, 2000; Cook et al., 2005; Tyler, 1998).

For most scholars, trust is relational, involving at least one individual making oneself vulnerable to another individual, set of individuals, or an institution that possesses the potential to do harm or betray. Trust implies a judgment of risk in conditions of uncertainty. Moreover, trust is seldom unconditional; it is given over specific domains. A client may entrust a banker with money but never consider leaving a child in the banker's care; citizens may entrust their lives to their government during wartime but not new taxes to legislators who promise improved public services.

Trustworthiness refers to certain attributes of a person or an institution and can exist even when trust is not at issue. Trustworthiness has two dimensions. The first involves the commitment to act in the interests of the trustor due to moral values about promise keeping, caring about the trustor, or incentive compatibility, or some combination of all three. The second dimension involves competence in the domain over which trust is being given. The trustworthy will not betray the trust as a consequence of either bad faith or ineptitude.

Research on Trust and Trustworthiness

The recent burgeoning of the social science literature on trust was initially a response to the perception that political and social trust is in decline and in part to an argument that trust is essential to a good society. The fact that there are now decades of responses to the same survey questions and that they indicate a reduction in both political and social trust in the advanced industrial democracies has generated an effort to explain and correct this trend. The emphasis on the importance of social capital and the claim that it, too, has decreased over time is another factor producing a focus on trust. Both Coleman (1990) and Putnam et al. (1993) included trust as a critical element in their original accounts of social capital.

Economists and organizational theorists have come to share Arrow's and others' view that more than formal incentives or

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32162-6

credible commitments may be necessary to account for productive internal relationships and innovative change within firms and organizations (Kreps, 1990; Miller, 1992; Kramer and Tyler, 1996). Sociologists, anthropologists, political scientists, and social psychologists are reconsidering the role of trust and trustworthiness in attempting to explain variation in cooperation (Barr, 2004; Gambetta and Hamill, 2005) and better governance (Fukuyama, 1995; Braithwaite and Levi, 1998; Tyler and Huo, 2002; Rothstein, 2011; Uslaner, 2002) are also reconsidering the roles trust and trustworthiness play.

Motivational Assumptions about Trust

Why does someone trust? There are at least four possible kinds of motivations: dispositional, moral, social, and instrumental.

In one widespread perspective, trust is a disposition, that is, some individuals are more inclined to trust or be trustworthy than others due to factors of personality or character. A dispositional view of trust leads to investigations of variation among the population in the propensity to trust and be trustworthy. There is little agreement in the trust literature, however, on the sources of such a disposition. It could be a result of innate character, childhood experience, learning and updating, instrumental manipulation, knowledge, social networks, social bonds, or social norms. The assumption of trust as a disposition fails to capture important elements of trust: trust always has both an object, the person, persons, or institution being trusted and a domain, what the person, persons, or institution is being trusted to do.

By some accounts, trust is motivated by morality. Individuals are trusting because they believe trust is the act of a good person. Trust as a virtue is a very unsatisfying account of motivation, however. To trust a conman or to trust a corrupt politician is hardly virtuous by any common language sense of virtue. Trust may reflect a normative ordering that demands deference and obedience to certain kinds of authorities, but it is important to maintain the distinction between the normative features of trust and the claim that trusting behavior is either morally motivated or a moral good. What may well have moral motivation is trustworthiness, which generally implies commitments, promise keeping, and obligations. We are more likely to consider someone trustworthy, ceteris paribus, when we believe they have ethical values that make it unlikely for them to betray a trust.

A third possible motivation is social in the sense that individuals derive their identity and self-esteem from their relations to others and thus trustor are trustworthy in keeping with their sense of self or to enhance social status, or both. Although the social motivation is intentional, the end sought has more to do with identity than with the achievement of some material benefit. This leads many of the adherents of social motivation to claim that it is neither interest based nor calculative.

A final kind of motivation is, in fact, instrumental and calculative. Trust is given when it is a means to a particular end and when there is reason to believe the trust will be rewarded. There is a positive expectation that the payoffs from taking a risk are worth the possible costs. It is easiest to trust when the risks are sufficiently low, and it may well be worth the risk when the returns are sufficiently high. There are some circumstances, however, when the cost of misplaced trust is so high that trust is rarely given or given only when there is considerable insurance. Trusting one's child to the care of another or investing one's life savings are two such cases.

The development of a reputation for trustworthiness can also be instrumental. The trustworthiness of an individual may enlarge one's possibilities for valued exchange and cooperation, and the trustworthiness of a government or organization may enhance the voluntary compliance and consent of those subject to its rules. Trustworthiness is also likely to increase the range of discretion given to the trusted, which is an issue of particular importance to agents, be they legislators or union officials or managers, acting on behalf of principals who lack the same intimate knowledge of the situation and the alternatives.

Conceptualizing Trust

In conceptualizing trust in order to engage in empirical research, two crucial distinctions exist: cognitive vs noncognitive trust; dyadic vs embedded trust. There is no empty cell in this matrix; a scholar can be concerned with either of the first and either of the second.

Assumptions about motivations are closely linked to whether the conceptualization of trust that informs empirical research is noncognitive or cognitive. Those who argue for motivations based on morality or social bonds tend to have a noncognitive approach, and those who argue motivations are instrumental generally have a cognitive view. The dispositional motivation can fit with either, depending on one's view of disposition formation.

The noncognitive conception of trust draws on the work of psychologists concerned with social identity, particularly Henri Tajfel and John C. Turner. It is advocated by contemporary social psychologists, such as Robyn Dawes, Tom Tyler, Rod Kramer, and Marilyn Brewer, and by social theorists, such as Allan Silver, who perceive trust as having a moral basis that contrasts with, although often complementing, the world of contracting and impersonal transactions. Individuals trust because of their attributions of motives to the person or institutions that must be trusted. If they attribute trustworthiness, they are more likely to trust, and they are most likely to attribute trustworthiness when there are social bonds or group identification between the trustor and the trusted. This perspective is rooted more in the emotions and morals of an individual than in the capacity to reason. It reflects personal relations and cannot be easily regulated by the impersonal relationships embodied in bureaucracy, market, or formal law. The cognitive conception of trust builds on the work of economists, political economists, and social exchange theorists, such as Kenneth Arrow, James S. Coleman Russell Hardin, and Diego Gambetta. The act of trust, of making oneself vulnerable, requires a thoughtful assessment of risk, informed by a rational expectation or a rational belief that the trusted will be trustworthy. Such an expectation or belief is generally grounded in knowledge of the other's past behavior or present motives and constraints. It can be affected by the existence of institutions, sanctions, and incentives that affect the probabilities that the trusted will act in the interest of the trustor.

The second distinction is between dyadic and embedded trust. Trust is relational in either case, but embedded trust

permits conceptualization of generalized trust and institutional trust, and not just trust at the individual level. Dyadic trust depends upon expectations about or social bonds with a particular other. Embedded trust rests in social networks and institutional arrangements that permit expectations about or social bonds based on the social roles, categorization, and rules affecting others.

Measuring and Observing Trust

The most common methods for studying trust include surveys, experiments, and case studies, sometimes but not always informed by formal models (see Levi and Stoker, 2000; Nannestad, 2008, for reviews). The surveys attempt to measure either political or social trust, but there is considerable controversy about how well they measure either. This is particularly true for the questions in the National Election Studies, which seem to be more about confidence in or positive assessment of elected officials than of political trust, and for those in the general social surveys, which seem to be tapping issues of social anxiety rather than social trust. The World Value Survey asks about both institutional and interpersonal trust, but its questions have similar limitations as the American versions. These major surveys do have the advantage of asking the same questions over the course of several decades, but there remains the issue of whether the time range covered is adequate to capture real changes in trust. Moreover, it is possible that people asked at one point in time understand a question differently than when they are asked at a later point in time. Surveys designed explicitly to capture the relationships of trust are even less likely than the major surveys to enhance understanding of changes in trust relations over time, and their questions still tend to be open to multiple interpretations.

Some survey work does offer insight into trust relations, nonetheless. For example, Toshio Yamagishi uses survey evidence, often in combination with experimental work, to provide some interesting observations on variations in trust within and across populations and countries. Comparing the United States and Japan, Yamagishi and Yamagishi (1994) conclude that the embeddedness of the Japanese, at least until recently, in such tight social networks meant that they did not need to develop the capacity for discerning who and what to trust that has long been characteristic of Americans. Others (e.g., Herreros, 2004; Levi et al., 2009; Levi and Sacks, 2009; Rothstein, 2011) use specific questions about trust in particular institutions to understand interactions between governments and citizens.

Experimental work on trust has different strengths and weaknesses. At their best, experiments can control for factors that might influence or be confused with trust and trustworthiness, they can investigate choice behavior and not just the attitudes captured by surveys, and they can be designed so as to clarify the conditions under which individuals are likely to trust. There have been interesting experiments linking trust to issues of exchange and collective action, and there has been some work attempting to get at the effect of dispositional variations within a population. Most of the experiments, however, focus on dyadic relationships, although there are experiments that investigate the operation of social networks. Moreover, much of the experimental work to date has conflated cooperation and trust. For these experiments to be more compelling, they need to clarify the roles that trust plays in producing cooperation rather than assuming that where there is cooperation, there is trust.

Several other approaches to the study of trust also deserve mention. The trust game and other formal models have proved useful to organizational theorists and economic historians attempting to understand the role trust plays in the relationships between principals and agents and in long-distance trade. There have been statistical analyses of indicators of trust in order to determine variation over time, and there have been case studies that attempt to capture the attributes of trustworthy government or trust that affects economic interactions and productivity in and across firms, industries, groups, regions, and countries. However, this research, although multiplying rapidly, is still in fairly early stages of development.

One of the most important advances in the research on trust is in the investigation of how differences in power relationships affect trust and trustworthiness (see, esp. Ensminger and Knight, 1997; Farrell, 2009; also see discussion in Cook et al., 2005, passim).

Is Trust a Useful Concept?

There is some question of whether a concept like trust is even necessary if the purpose is to explain phenomena that rely on impersonal, multiperson, and anonymous interactions. Williamson (1993) makes a case that it is not; to him trust exists only in personal relations with incentives, interests, and institutions regulating political, market, and large-scale social interactions. Silver (1985), coming from a totally different perspective, offers a similar argument. Hardin (1998) claims that trust, as he defines it, can exist only in the rather limited set of cases where the trustor has sufficient knowledge of the trusted to believe that their incentives are compatible; he is wary of such concepts as trust in the government. Levi (2000) claims that trust is not always the solution to distrust. There are, after all, numerous functional alternatives to trust that rely more on assurance or coercion than on trust, such as, third-party insurers, contracts and other legal enforcement devices, professional ethics, fictive kinship, and a variety of social networks and institutional arrangements.

The argument of the social identity theorists and those who come out of the sociological tradition of Durkheim or the liberal political tradition of Locke is that trust most certainly matters and is, in fact, essential to a well-ordered society. It is constitutive, in this view, of the moral and personal glue that enables modern societies to function (Seligman, 1997). These scholars tend to decry the loss of trust and seek to halt its further decline by advocating the maintenance and creation of community, republicanism, and more personalized interactions, even in large-scale organizations. On the other hand, those relying on instrumental and cognitive theories treat the work trust does as an empirical question. Relationships of trust are but one of many means to achieve given ends, and whether they are the best means is still open to considerable research and debate.

Abstract

This article examines what trust is, its role, and value in human lives, and when it is justified. It surveys accounts of trust, ranging from the relatively open, which equate trust with reliance, through to more restrictive accounts, which insist that reliance be accompanied by confidence, to highly restrictive accounts which demand that the reliance involved in trust be grounded in specific assumptions about the motivation of the one trusted, such as that they have goodwill toward the truster. It examines whether we need reason to trust, and if we do what kind of reasons can make trust rational.

Three central questions in the philosophy of trust are What is the role and value of trust in human lives? How are trust and trustworthiness to be analyzed? When is trust justified? This article addresses each question in turn; however, the answers to them are interconnected. Any plausible account of what trust is must be capable of explaining its role and value. Any account of what trust is sets constraints on when and how trust can be justified and, since trust and trustworthiness are paired concepts that must be analyzed in tandem, also sets constraints on the analysis of trustworthiness. In the philosophical literature on trust, there is general agreement that trust has both instrumental value for securing the goods of cooperation and intrinsic value as a constitutive part of relationships, such as friendship, that are valuable in themselves. There is also general agreement that trust is a three-place relation: A trusts B to do Z. Disagreement emerges, however, regarding how trust is best analyzed. The least restrictive analysis of trust equates trust with reliance; a more restrictive account insists that reliance be accompanied by confidence; yet more restrictive accounts of trust demand that the reliance involved in trust be grounded in specific assumptions about the motivation of the one trusted, such as that they have goodwill toward the truster, care about maintaining a relationship with the truster, or recognize that they are liable to be held accountable for their failure to act in the way counted on.

The Role and Value of Trust

Trust makes it possible for us to enter, willingly and with confidence, into relationships of dependency. As finite and social creatures, we are dependent on one another in multiple ways. The food we eat typically comes to us having passed through many hands in the stages from production, to distribution, to purchase. Our health rests on the knowledge and professional competence of a host of individuals and institutions, our happiness on the goodwill of friends and strangers, our projects on the contributions of others, our knowledge on testimony and deference to experts, our economies on the competences of government institutions, and so on, through the myriad of dependencies that make our lives possible. In youth and in old age, dependency is even more pronounced.

Dependency brings with it risk: one may be left worse off than one would have been had one not depended. Trust makes such risks seem worth the taking. Trust is required for the proper functioning of divisions of economic and epistemic labor, divisions that can greatly increase the speed with which goods, including knowledge, are produced and, thus, the complexity and scope of the projects that can be undertaken. In these ways, trust, when met with trustworthiness, is shown to have instrumental value insofar as it contributes to bringing about the goods of cooperation.

Social scientists argue that trust is an important form of social capital, the absence of which hampers economic development (Putnam, 1995; Fukuyama, 1995; but for an opposing view see Hardin, 2002). Societies with high levels of trust present more economic opportunities than societies with low levels of trust. Moreover, trust enables transaction costs to be lowered by reducing the need for expensive substitutes for trust such as legal remedies and close monitoring of performance. Monitoring and legal remedy presuppose a relatively determinate understanding of what counts as an acceptable discharging of the responsibilities of a dependency relationship. Trust allows the truster to give trustees discretionary powers with respect to how they fulfill that trust (Baier, 1986: p. 237). Discretionary powers greatly enhance the usefulness of dependency relationships: often the truster cannot precisely specify in advance what it is that they are counting on the other to do either because the truster does not have the ability to predict the contingencies that must be planned for (think of the discretion given to babysitters), or because they do not have the knowledge to specify what would count as an appropriate response to such contingencies. The limits of the trustee's discretionary powers are only vaguely specified and this vagueness opens up the possibility for abuse – an untrustworthy trustee might conceal subtle breaches of trust as appropriate uses of her discretionary powers. Assigning discretionary powers thus brings with it additional risks as well as benefits.

Well-placed trust not only has objective benefits assessable in terms of the results of successful dependencies, it also has subjective benefits. Trust lets us inhabit a simpler and less threatening world in which we need not plan for every contingency (Luhmann, 1973). Trust enables us to forgo anxious monitoring of performance and to feel secure in our interactions with others.

Trust's value is not exhausted by the objective and subjective benefits it brings. Trust also has intrinsic value insofar as it is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63088-X

constitutive of relationships that are valuable in themselves, such as friendship. Likewise, preemptive distrust, especially when incurred in virtue of one's membership in a negatively stereotyped group, not only has instrumental disvalue insofar as those unfairly distrusted are cut off from the benefits of joint projects that presuppose trust, it also communicates disrespect. The value we assign to being trusted and the disvalue we assign to being distrusted is thus not exhausted by the consequences of others holding those attitudes toward us.

This brief description of the role and value of trust in our lives points to the significance of developing an account of what trust is and also sets constraints on that account: any account of trust must be able to explain how it can fulfill the roles and have the value that it has, or, failing that, must explain how we could be confused about trust's role and value.

Accounts of Trust and Trustworthiness

While trust might appear to be a dyadic relation of the form 'A trusts B' (e.g., the citizens trust their government), trust is best analyzed as a three-place relationship: A trusts B to do Z (Baier, 1986; Holton, 1994). Even among close friends, trust seldom extends to all domains of interaction and there is typically some background assumption in place about that with respect to which the other is trusted. The triadic nature of trust shows that trust need not be an all or nothing affair – one can trust with respect to the performance of some actions, but not others. This opens up the possibility of incrementally increasing trust by gradually extending the range of actions that the other is counted on to do. Paradigmatically, the 'A' and 'B' of the schema 'A trusts B to do Z' stand for persons. However, nonnatural agents, such as corporations and governments can also fill either role, as can perhaps nonhuman animals. Furthermore, on some accounts of trust, but not others, things such as machinery and ropes can occupy the role of B.

Accounts of trust can be taxonomized along two independent axes. The first axis concerns the attitude or stance that trust is taken to be. Is trust actionlike, belieflike, affective attitude-like, some combination of all three, or something different again? The second axis concerns the motivation that trust tacitly ascribes to the one trusted. This axis marks disagreement over the nature of trustworthiness. Accounts can be placed on a graded scale with respect to how open or restrictive they are about the motivational structure that trust tacitly ascribes to the one trusted. A thin account places no restrictions at all on the motivations of the trustworthy; highly restrictive accounts demand that the trustworthy act from goodwill toward the truster (Baier, 1986; Jones, 1996) or from moral integrity (McLeod, 2002). A variety of positions lie in between these extremes.

The simplest account of trust, trust-as-reliance, is open with respect to motivation and emphasizes the respects in which trust is actionlike and seemingly something we can will. On this model, agents can trust machinery and ropes as well as other agents, natural and artificial. However, agents will count as trusting even when they do not expect a favorable outcome. For example, someone may decide to rely on a frayed rope that they do not believe is strong enough to hold them – perhaps it is better to risk probable death or injury from a fall than certain death from the oncoming fire. A trust-as-reliance model conforms to ordinary linguistic usage, for it would not be incorrect to say that such a person decided to trust the rope rather than to take their chances with the fire. Nevertheless, the trust-as-reliance model identifies too heterogeneous a class of dependencies to explain trust's role and value in human lives. For example, the claim that trust contributes to social capital and reduces transaction costs is false if trust is understood as reliance with or without confidence. Someone who relies while expecting the worst will be on the lookout for alternatives to such reliance and will cease to rely once another option emerges. Such wary and reluctant dependence cannot be thought of as social capital. If we are to understand the value of trust, we need a richer conception of it.

According to Thomas Hobbes, "[t]rust is a passion proceeding from the belief of him whom we expect or hope for good, so free from doubt that upon the same we pursue no other way" (1994[1650]: IX 9). Call this the *trust-as-confidence* model. Hobbes emphasizes the affective nature of trust, whereas contemporary trust-as-confidence models emphasize cognitive-based risk assessment. Thus Diego Gambetta writes:

> Trust (or, symmetrically, distrust) is a certain level of subjective probability with which an agent assesses that another agent or group of agents will perform a particular action, both *before* he can monitor such action (or independently of his capacity ever to be able to monitor it) *and* in a context in which it affects *his own* action.
>
> Gambetta, 1988: p. 217, original emphasis

Confidence can be grounded in all sorts of properties of the one trusted. An agent might trust someone to do Z because they are motivated by self-interest, goodwill, fear, or just because they are in the habit of doing Z. Trust-as-confidence remains a comparatively thin conception of trust. It is able to explain the instrumental value of trust in enabling cooperation, but is unable to explain the ways in which we take trust to have intrinsic value or to explain why we should be distressed by preemptory distrust. The expressive regard shown by trust or distrust can be explained neither by the motivation trust attributes to the one trusted, since any motivation will do, nor by the attitude that trust is, whether this attitude is understood as cognitive or affective.

Richard Holton's account of trust fares better at explaining the intrinsic value of trust while nevertheless remaining open ended about the motivation that trust tacitly ascribes to the one trusted. Drawing on Peter Strawson's (1974) notion of reactive attitudes – those attitudes that we take toward people when we view them as fellow agents who are to be held accountable for what they do – Holton argues that trust is reliance invested with reactive attitudes: "When you trust someone to do something you rely on them to do it and you regard that reliance in a certain way: you have a readiness to feel betrayal should it be disappointed, and gratitude should it be upheld" (Holton, 1994: p. 67). When you trust, you do not treat the other as a mere regularity to be worked with or around, but treat them as a fellow agent, subject to normative expectations (or expectations *of*) and not merely predictive expectations (or expectations *that*). (For the distinction between normative and predictive expectations, see Hollis, 1998.) However, it fares less

well than trust-as-confidence accounts in explaining the instrumental value of trust, since, like simple trust-as-reliance accounts, it groups together both confident and reluctant reliances. It is possible to have the dispositions to reactive attitudes that Holton claims are constitutive of trust toward reliances that have been undertaken unwillingly and only because no safer choice presented itself. Merely having dispositions to reactive attitudes does not facilitate cooperation. Confidence seems characteristic of trust, suggesting that prospects for an account of trust fully able to explain its role in our lives might lie in refining and further restricting a trust-as-confidence view.

Russell Hardin's encapsulated interest model of trust proposes to distinguish trust from mere reliance in the following way: "it is trust I have, and not merely inductive expectations *if* I think that you have a reason in some way grounded in me for fulfilling my trust. For example, I might well expect you to rise every morning at 7:00 because I know your habits very well, but I do not trust you to do so if I have no reason to suppose that you do so somehow on my behalf" (1998: p. 12). The reasons for the one trusted performing as they are being counted on to do must make reference to the truster. The reference to 'on my behalf', should not, however, be taken to indicate that Hardin thinks trust requires attributing to the one trusted a direct concern for the truster's welfare. Hardin thinks that typically the one trusted will have self-interested reasons for not letting the truster down. This interest frequently derives from a desire to maintain an ongoing relationship with the truster.

Other, yet more restrictive, accounts see reliance on self-interest as incompatible with trust. Goodwill-based accounts claim that trust tacitly imputes goodwill to the one trusted. According to Annette Baier's influential account, trust is "accepted vulnerability to the other's possible but not expected ill will (or lack of good will) towards one" (Baier, 1986: p. 234). The distinction between trust and mere reliance is the difference between "reliance on their goodwill towards one, as distinct from their dependable habits, or only on their dependably exhibited fear, anger, or other motives compatible with ill will towards one, or on motives not directed on one at all" (Baier, 1986: p. 234). A somewhat different account that shares the intuition that goodwill is central but that stresses the importance of affect or emotion is offered by Jones (1996), who defines trust as an affective attitude of optimism that the goodwill and competence of the other will extend to cover the domain of your interaction, together with the confident expectation that the other will be directly and favorably moved by the thought that you are counting on them. Other theorists (McCleod, 2002; Mullin, 2005) argue that trust tacitly assumes a commitment to shared norms, or that trust tacitly ascribes obligations to the one trusted (Nickel, 2007) or that trust presupposes that the one trusted will act as they are being counted on in part out of recognition that they will be held accountable should they fail so to act (Walker, 2006: p. 80).

The richer the conception of trust, the more likely it is to be able to explain why we take trust to have intrinsic value and the more satisfying the picture it gives of the role of trust in interpersonal relationships such as friendship. Richer conceptions can also explain why trust should be instrumentally valuable, for clearly joint projects will go better when participants have goodwill or shared values. These advantages come at a cost, however, since the richer the conception of trust, the less likely trust is to be in good supply once we step outside the realm of close interpersonal relationships. Highly restrictive accounts of trust have their natural home in theorizing about face-to-face relationships where knowledge about the likely motivations and evaluative outlooks of those with whom we interact is more easily come by. Less restrictive accounts seem better equipped to address trust in more impersonal contexts, including institutional contexts, where it seems we willingly and confidently rely without having much information about the reasons others have to act or about the internal workings and structures of institutions. There are thus advantages and disadvantages to each of the available philosophical accounts of trust and no single account is able to offer a wholly satisfactory explanation of the role and value that trust has in our lives. Perhaps the explanation for this is that we do not have a single pair of trust and trustworthiness concepts, but instead use different concepts in different contexts for difference purposes. If this is so, then we may have to give up on the project of coming up with a single account of trust, and focus instead on analyzing trust in specific contexts.

Justified Trusting

If trusting is to bring about the goods of cooperation, it must be met with trustworthiness. Trust in the untrustworthy breeds exploitation and abuse. Moreover, the costs of misplaced trust are frequently borne by others more vulnerable than the truster – think, for example, of child abuse. Call trust that succeeds in being directed toward the trustworthy 'apt' or 'fitting' trust. Just as true belief must be distinguished from justified belief, apt trust must be distinguished from justified trust. Sometimes, despite our trust being well grounded in evidence available to us, we nonetheless have the misfortune to trust someone who is not trustworthy; other times, we escape getting burned despite trusting unwisely. The problem of being justified in one's trust raises a cluster of questions, some theoretical and some practical: What kinds of reasons can provide grounds for trust? How much evidence of trustworthiness, if any, do we need before our trust counts as justified? How can trustworthiness be promoted and better communicated so that would-be trusters will know where to place their trust and where not? I address each of these questions in turn.

How a theorist analyses trust sets constraints on what they can say about when trust is justified and on the kind of reasons that can justify it. If a theorist holds that trust is fully or partly constituted by a belief that the other is trustworthy, then they must also hold that trust is justified by evidence that would support a belief in trustworthiness. Trust cannot be justified by instrumental or moral reasons, since these are the wrong kind of reasons to support belief in trustworthiness (Hieronymi, 2008).

The problem of what reasons are capable of justifying trust can be bought into focus by considering therapeutic trust, or trust undertaken in the hope of eliciting trustworthiness from someone whose past track record would not support a judgment that they are trustworthy (Horsburgh, 1960). Theorists who take trust to be partly or fully constituted by a belief that the other is trustworthy (Hardin, 2002; Hieronymi, 2008) must

deny that therapeutic trust is genuine trust. However, consider the case of a parent who decides to let their teenaged daughter stay at home overnight without supervision, even while recognizing that she may again show herself irresponsible. It seems that the parent trusts in order to bring about the very trustworthiness that would make their trust apt. Such strategies work, when they do, by eliciting trust responsiveness on the part of the one trusted. Pettit defines trust responsiveness is the "disposition to prove reliable under the trust of others" (Pettit, 1995: p. 203) and argues that it can be grounded in a variety of elements in an agent's motivational set, including positively valued traits such as loyalty, virtue, and prudence, as well as traits that are not so well regarded, such as desire for the good regard of others. Another psychological spring for trust responsiveness is to be found in the agential scaffolding provided by the optimistic truster's image of ourselves as trustworthy, an image we then try to live to up to (McGeer, 2008).

Trust responsiveness has a negative corollary in distrust responsiveness. If others become aware of our distrust, either because we refuse dependency, or because we engage in intrusive surveillance, we risk undermining the positive effect of trust responsiveness and, further, we risk alienating the one being monitored and thus activating untrustworthiness. Surveillance generates resentment, undermines internal motivations toward trustworthiness, and encourages even the honest to attempt to beat the surveillance system (Kramer, 1999: p. 591). It is widely observed (e.g., Baier, 1986; Baker, 1987; Jones, 1996) that trust and distrust are self-confirming. Trusting is often met with perceived trustworthiness and distrust with perceived untrustworthiness. In part, this is to be explained by perception – someone who trusts will interpret the one trusted's actions through the lens of that trust. An action that might have been seen as indicative of untrustworthiness will be explained away as compatible with trustworthiness (Jones, 1996). Equally, someone who distrusts will tend to interpret actions that could be given a favorable interpretation as nevertheless revealing motives indicative of untrustworthiness ('what does she want from me that she is being so nice?'). In part, it is to be explained by opportunities to prove oneself trustworthy: where possible, one steers clear of those one does not trust and so they are never given the chance to demonstrate their trustworthiness. But, in large measure, the self-fulfilling nature of trust and distrust is to be explained by trust responsiveness and its corollary distrust responsiveness.

Once we settle the question of what kinds of reasons – only evidential reasons, or also goal directed reasons or moral reasons – can justify trust, the question remains how strong those reasons must be. How much, if any, evidence do we need of the other's trustworthiness before our trust is justified? How confident, if at all, must we be that goal directed trust will be met with trust responsiveness before instrumental trust, if indeed it is a genuine form of trust, can be justified? Some claim that, on moral grounds, we should begin from a default stance of trust and move from this default only if we have positive evidence of untrustworthiness (Lagerspetz, 1998). Others argue that this question lacks a general answer. How much, and what sort of information agents need before it is rational for them to trust depends on the climate of trustworthiness they inhabit, on what it is that the other is being trusted to do, and on the cost of misplaced trust (Jones, 1996). When the climate is sufficiently bad it might be reasonable to begin from a default stance of distrust and move toward trust only when there is considerable evidence of the trustworthiness of the other. Some actions, such as refraining from harming others as they go about their business, require only minimal decency and no particular competence and thus, unless the climate of trust has broken down completely, it can be assumed that trust is warranted. Other actions will be such that their performance demands competencies or motivational resources that cannot be assumed to be widely distributed – in such cases, the truster will require specific evidence about the trustworthiness of the other. Such evidence may take the form of marks that indicate that the trustee belongs to some subset of the population in which trustworthiness with respect to the required action will be the norm (e.g., board-certified surgeons), or it may take the form of evidence about motivations and competencies specific to the trustee. The consequences of misplaced trust also affect how much evidence is required for rational trust – holding constant climate and kind of action to be performed, it will take more information before I am justified in trusting when I risk a grave loss should the other prove untrustworthy than when the loss is less.

The problem of justified trust has a practical face as well as theoretical one: how can we create societies in which our trust is more likely to be met with trustworthiness and how can would-be trusters work out where to direct their trust appropriately? Intelligently designed systems of accountability can address both problems (O'Neill, 2002, 2005). Trust should not be blind and is not necessarily in tension with accountability. A well-designed system of accountability addresses three concerns: it can help create trustworthiness in the domain it regulates by creating competence (e.g., through systems of training and credentialing) and by creating a confluence of motives toward acting in the ways expected (e.g., through watch dog and oversight structures); it can increase awareness, on the part of those we would trust, of the extent and limits of their competences, and so of the domains in which they are able to respond to trust with trustworthiness; and it can communicate to would-be trusters who is likely to be a fit target for their trust. However, to play these roles, a system of accountability must be well designed. Poorly designed accountability systems (and there are many) undercut internal motivations toward trustworthiness by replacing them with external incentives and penalties, risk activating distrust responsiveness, and substitute proxy measures, which can be checked off by people without field-specific knowledge, for real markers of performance, thereby creating perverse incentives (O'Neill, 2005).

Trustworthiness, like trust, has three-place structure: A is trustworthy with respect to B, regarding action (or action type) Z. One kind of thing with respect to which we can be trustworthy is communicating to would-be trusters those areas in which others may place their trust in us (Jones, 2012). Agents willing to do this help would-be trusters place their trust wisely by signaling which dependencies they will welcome and which they will not. They thus take on some of the burden of helping would-be trusters be justified in their trust. It is not always easy to communicate effectively that one can be trusted. Often trustworthiness cannot be conveyed

directly: "'Trust me!' is for most of us an invitation which we cannot accept at will – either we do already trust the one who says it … or it is properly responded to with, 'Why should I and how can I until I have cause to?'" (Baier, 1986: p. 244). Trusted third parties can thus be important brokers for new trust relationships.

Though some ways of communicating trustworthiness are formal and institutionally backed (e.g., board certification for surgeons), many are informal and rest on self-presentation, body language, and the workings of tacit assumptions regarding who can be trusted by whom for what. Sometimes, attempts to communicate one's trustworthiness in a domain fail because uptake is blocked by stereotype and prejudice (Fricker, 2007). In a related but reversed phenomenon, members of positively viewed groups can be the recipients of unearned trust simply in virtue of their social identities. Prejudice and stereotype are thus major obstacles to justified trusting.

Conclusion

Perhaps the central question in the philosophy of trust is whether and how to separate trust from mere reliance. All plausible philosophical accounts of trust attempt some form of separation between these two phenomena, but there is nonetheless significant disagreement regarding: (1) the attitude they take trust to be and whether this is best analyzed on the model of action, belief, emotion, some combination, or something else again; and (2) the motivation they take trust to tacitly impute to the one trusted. Analyses of trust set constraints on what can be said about trustworthiness and also on when, and by what sorts of reasons, trust can be justified. Answers to these theoretical questions have practical implications for devising strategies to increase the likelihood that trust will be met with trustworthiness.

Abstract

The natural sciences occupy a special place in modern culture. Scientific knowledge substantially defines our culture's notion of truth, and the overwhelming credibility of that knowledge in our society is widely taken to be sufficiently explained by its truthfulness. The social sciences have traditionally concurred in these assessments and have paid the natural sciences the compliment of emulation. Yet that emulation has largely proceeded by way of textbook idealizations of natural scientific knowledge and how it is produced, while the idealizations themselves – produced by both academic epistemologists and reflective scientists – are much more variable than is generally supposed. It has not been until fairly recent times that social scientists have attempted wholly naturalistic inquiries into how scientific knowledge is produced and how it comes to be believed. The sociology of scientific knowledge that emerged from the early 1970s purposely set aside epistemological evaluation and took as its primary task understanding scientific credibility. How is it that scientific claims succeed, or fail, in being believed? This article surveys a number of considerations that recent social studies of science have found to be widely relevant to the interpretation of scientific credibility.

The natural sciences occupy a special place in modern culture. Scientific knowledge substantially defines our culture's notion of truth, and the overwhelming credibility of that knowledge in our society is widely taken to be sufficiently explained by its truthfulness. The social sciences traditionally have concurred in these assessments and have paid the natural sciences the compliment of emulation. Yet that emulation largely has proceeded by way of textbook idealizations of natural scientific knowledge and how it is produced, while the idealizations themselves – produced by both academic epistemologists and reflective scientists – are much more variable than generally is supposed. It has not been until fairly recent times that social scientists have attempted wholly naturalistic inquiries into how scientific knowledge is produced and how it comes to be believed. The sociology of scientific knowledge that emerged from the early 1970s purposely set aside epistemological evaluation and took as its primary task understanding scientific credibility. How is it that scientific claims succeed, or fail, in being believed? This article surveys a number of considerations that recent social studies of science have found to be widely relevant to the interpretation of scientific credibility.

Scientific Truth: As Evaluation and Resource

'Truth' appears only occasionally as a vernacular term, nor does the special notion of intellectual quality the word connotes in academic philosophy figure much in everyday usages. Professional epistemologists worry how to reliably sort genuine knowledge from belief, opinion, or mere knowledge-claims, and this is the major context in which academic theorizing about truth takes place. Many theorists are agreed that knowledge (properly so-called) is 'true belief,' but there is no philosophical consensus about the definition of truth, about the domains in which we can expect to have genuine knowledge, about the grounds for establishing truth, or, indeed, about what it is that can be said to be true (propositions, facts, theories, thoughts, concepts, beliefs, etc.). The major battle pitches correspondence theories against coherence theories of truth, while skirmishes are fought along the margins between conventionalist, pragmatist, performative, redundancy, disquotational, and miscellaneous other theories (or antitheories) of truth.

In ordinary life, the word truth often crops up as a special-purpose term whose employment indicates that some out-of-the-ordinary guarantees are being sought for promises, professions, or claims to knowledge, or that there is some specially occasioned doubt about their genuine status, as in legal proceedings when witnesses are ceremonially sworn 'to tell the truth, the whole truth, and nothing but the truth' (Lynch and Bogen, 1996), or in intimate social relationships when one has misgivings about one's lover's sincerity and looks for explicit warrants of affection: 'When my love swears that she is made of truth,/I do believe her, though I know she lies.' Perhaps even more commonly, everyday actors, and even philosophers in many circumstances, use the words true or truth just as a way of giving added emphasis or value to assertions of what is the case, the lexical equivalent of thumping the table.

The category of everyday actors may be taken, for the most part, to include professional natural scientists engaged in their ordinary knowledge-producing practices. While their expert employments generate knowledge whose content, methods of production, and value are widely said to differ markedly from lay beliefs about the world and lay modes of cognition and evaluation, epistemological reflection does not occupy much of scientists' time, nor is it customary for them to engage in metascientific inquiries into the nature and status of their knowledge. The result is a situation in which the bodies of expert knowledge that are widely taken as the touchstone of truth in our culture, and the object of vast amounts of epistemo- logical reflection by philosophers, tend to be produced by practitioners who rarely concern themselves reflectively or systematically with the nature of their knowledge, or its standing vis-à-vis nonexpert knowledge, or with the methods that produce their so-highly-valued knowledge. The paucity of practitioners' reflection on the nature and quality of their knowledge is an important feature of the modern natural sciences, and the social sciences and humanities are quite different in this respect.

Practicing natural scientists seem to take scarcely any notice of epistemologists' debates or dicta. Indeed, in the natural sciences, epistemological and metascientific musings, as well as sociological reflections, are often taken as a sign of emeritus (or, unkindly, 'past it') standing. They are sometimes explicitly condemned as irrelevant, unprofessional, or even pathological: it may be what philosophers or sociologists do, but (it is said) it is not what practicing scientists ought to do. In the nineteenth century the experimental physiologist Bernard (1865/1957, p. 49) vigorously disengaged the scientific production of truth from scientists' possible reflections on truth or on how truth was produced: 'To find scientific truth, we … have little need to know how our mind reasons; it is enough to let it reason naturally.' Bridgman (1955, p. 157) was one of many modern physicists taking a jaundiced view of philosophers' attempts to characterize both scientific truth and scientific method: philosophers' 'abstractions' tended to attract a 'veneration' that was wholly undeserved. C. P. Snow – a one-time chemist and latterly a spokesman for science – bumptiously admitted that 'By *truth*, I don't intend anything complicated .I am using the word as a scientist uses it. We all know that the philosophical examination of the concept of empirical truth gets us into some curious complexities, but most scientists really don't care' (Snow, 1961, p. 247). Albert Einstein famously celebrated, rather than condemned, what he took to be the fact 'that the man of science is a poor philosopher.' If, Einstein (1936/1954, p. 296, 318) said, 'you want to find out anything from the theoretical physicists about the methods they use, I advise you to stick closely to one principle: don't listen to their words, fix your attention on their deeds.' Moreover, the small number of empirical studies we now have of natural scientists' grasp of the principles of formal logical reasoning strongly suggests that the power and reliability of scientific knowledge do not spring from the superior reasoning capacities of individual scientists (Mahoney, 1979; Mahoney and DeMonbreun, 1977).

When one considers the content of such scientists' musings about truth as are occasionally produced, further problems are posed for any social science wishing to model its epistemic goals on those of the natural sciences. Many academic, and some lay, views of the natural sciences point to scientific facts, laws, and theories as enjoying the status of accredited truth, and to the proper goals of scientific inquiry as the production of such truth. Yet important strands of practitioners' metascientific stipulations identify the goal of producing truth as illegitimate, and such special status for scientific representations as a lay misunderstanding of what genuine science is about. Some scientists do indeed say that science aims at, or even arrives at, one universal truth. However, others say that the truths of sciences are plural, or that science is just 'what works' and that truth – or even correspondence with the world – is none of their concern – just 'what stands the test of experience,' or 'what seems to be the case to the best of our current efforts and beliefs.' Oppenheimer (1954, p. 4) followed the nineteenth-century Scientific Naturalists in warning science to shun 'metaphysical' notions like 'real' and 'ultimate' in talking about its concepts and theories: if we say that physical theories are true, we must say so in a carefully qualified non-metaphysical sense. Einstein (1929/1954, pp. 261–2) found it 'difficult even to attach a precise meaning to the term "scientific truth." Thus, the meaning of the word "truth" varies according to whether we deal with a fact of experience, a mathematical proposition, or a scientific theory.' Bridgman (1955, p. 158) noted that 'In physics we have been forced to recognize … that there are different kinds of truth, depending on the method used for establishing "truth."' Bridgman's student Oppenheimer (1954, p. 95) vigorously agreed: 'Perhaps only a malignant end can follow the systematic belief that all communities are one community; that all truth is one truth.' Just as epistemologists espouse widely varying conceptions of truth, so too do those natural scientists occasionally drawn to philosophizing, while most practicing scientists seem well content to leave philosophy to the philosophers.

From Truth to Credibility: Science as a Topic

For these reasons alone, the posture of the social sciences vis-à-vis the natural sciences, and, especially, with respect to emulating their truth-criteria, is problematic. Should social scientists really wish to pattern themselves on the natural sciences in order to solve problems of intellectual identity, authority, and quality, they would find it no easy thing to do, such is the diversity of natural scientific practices and sensibilities, and of professional metascientific stipulations about the natural sciences (Mills, 1959, pp. 119–31). This diversity is seldom adequately reflected in textbook accounts of scientific method and scientific knowledge, nor is it apparent when one particular natural science – typically some version of modern physics – is made by fiat to stand for all the rest (Shapin, 1999a). Yet once this variability is properly appreciated, it becomes clear that the social sciences will have to make their own claims to knowledge and support them as best they can, using whatever resources and warrants are available and are deemed legitimate.

However, misguided emulation is not the only possible mode of social scientific engagement with the natural sciences. Social scientists can study the cultures of the natural sciences, seeking to understand how a range of natural scientists collectively produce their knowledge, how they make it persuasive, and how they render their intellectual evaluations. This has been the task taken up by the sociology of scientific knowledge over the past 30 years or so. Indeed, the founding gesture of modern sociology of scientific knowledge was the rejection of epistemological evaluation as the proper basis for sociological accounting. Traditional sociology of knowledge – descended from Marx and Mannheim – had reckoned, almost as a matter of course, that true and false beliefs should be explained differently. False beliefs might customarily be referred to distorting social and psychological factors, while the truth of true beliefs – their adequate evidential base, or their logical coherence, or their production and assessment using transparent and impersonal rational methods – could count as its own sufficient explanation (Mannheim, 1936, pp. 239, 261; Phillips, 1974). It was not considered that much of sociological interest could be said about true beliefs, and therefore about the body of currently accepted scientific knowledge. That is why traditional sociology of knowledge explicitly exempted accepted scientific beliefs from its scope.

Bloor's (1976/1991) *Strong Programme* in the sociology of scientific knowledge enjoined sociologists professionally to set aside external judgments of truth and falsity and to explain the acceptance of both reputed true and reputed false beliefs using the same resources. It was not that sociologists were to account all beliefs of equal value – that would itself be an act of epistemological assessment – rather it was that sociologists, in doing sociology, should be impartial with respect to the reputed truth or falsity of beliefs, as true and false seemed to the individual sociologist or as the beliefs were routinely sorted in the culture of which the sociologist was an everyday member. Bloor here identified generally acknowledged academic virtues that would flow from adhering to this maxim of method and academic vices that had traditionally stemmed from rejecting it. On the one hand, it was not the proper business of the social scientist to engage in epistemological assessment; on the other hand, inscribing external judgments of truth and falsity in social scientific accounts illegitimately blocked the free inquiry and rendered explanation circular. In Bloor's view, the sociologist could and should be as curious about why some cultures – in this case, our own – classify the cassowary as a bird as they had traditionally been about such cultures as the New Guinea Karam that classify what we call cassowaries and what we call birds in different taxa (Bulmer, 1973; Barnes, 1973; Barnes and Bloor, 1982).

The *Strong Programme* did not mean to ban consideration of truth and falsity but, rather, to encourage sociologists to take a fuller naturalistic interest in the problem of how actors themselves sorted beliefs as between true and false. Actors' truth- judgments, or judgments of what is the case about the world, were not to be just an asymmetrical resource but a central topic of sociological inquiry. Or, put another way, this newer form of the sociology of knowledge placed the credibility of beliefs at the center of its intellectual agenda. Suppose, taking up the toy taxonomical example, one asked a member of the Karam why it was that they classified cassowaries in a different taxon than the rest of what we call birds. After translating the question into their own vocabulary, the Karam might reply in the prevalent folk- epistemological idiom, rolling their eyes, or saying that the matter is self-evident, or citing all sorts of obvious and important empirical differences between the big, ground-dwelling cassowary and the small, aerial bird-of-paradise. Pressed further, the Karam might point to the views of legitimately respected elders and experts, as sanctioned by custom and use. And so it might plausibly strike the Western social scientist that the grounds of credibility of Karam taxonomy had a lot to do with authority, custom, socialization, and with the vehicles that routinely transmit and maintain culture, including classificatory culture.

Patterns of routine socialization are not the only considerations in explaining structures of credibility – indeed, the anthropologist who most closely studied the particular case in question laid greatest stress upon the supposed functions of Karam taxonomy in sustaining social order (Bulmer, 1973) – but socialization is everywhere pertinent to giving accounts of what people find credible, whether the socializing agencies are those of Karam agricultural society or departments of zoology in modern American universities (Barnes, 1972: p. 271). So, if the sociologist were to put a parallel classificatory question to an academic practitioner of modern Linnaean taxonomy, it is arguable that the responses received would structurally resemble those supplied by the Karam, and, again, patterns of socialization would be major aspects of any explanation the sociologist might offer of the grounds of credibility of taxonomic beliefs in our own expert culture. Note that the empirical adequacy of Linnaean classification is not thereby disparaged – though there is substantial controversy about its theoretical and evidential adequacy within expert taxonomic culture – but the sociologist of scientific knowledge holds that standards of empirical adequacy, and the particular goals towards which classificatory schemes are oriented, are themselves objects of socialization (Dean, 1979). All institutionalized beliefs about nature are causally connected to reality, and 'all beliefs are on a par with one another with respect to the causes of their credibility. It is not that all beliefs are equally true or equally false, but that regardless of truth or falsity the fact of their credibility is to be seen as equally problematic' (Barnes and Bloor, 1982, p. 23; Barnes, 1992). The 'paradigms' of what Kuhn called 'normal science' are exemplary items of technical knowledge, and they are also learned bits of culture. Since this culture is transmitted in authoritative institutions, the sociologist's whole range of resources for dealing with socialization and its consequences is, therefore, pertinent to explaining the credibility of technical scientific knowledge among expert practitioners (Polanyi, 1958; Kuhn, 1962; Barnes, 1982).

Accounting for Credibility: Mundaneness and the Moral Order

So the sociologist of scientific knowledge studies credibility. What actors find credible, and how they account it credible, may include specially occasioned judgments of truth or they may not. The distinction is not crucial, since the credibility of any such reflective truth-judgments (by way of correspondence or coherence or any other criterion) may also be a matter for inquiry. The sociologist, qua sociologist, here differs from the philosopher (and maybe from the layperson): 'Instead of defining (knowledge) as true belief, knowledge for the sociologist is whatever people take to be knowledge,' what they find credible (Bloor, 1976/1991, p. 5). And patterns of socialization are everywhere pertinent to giving a sociological account of the credibility of beliefs. These are, so to speak, ground-conditions for the sociological study of science, and, as such, they are not themselves answers but necessary conditions for arriving at particular answers to particular questions about particular bodies of knowledge – answers that are sociologically proper, constructive, and interesting. For sociologists to say that they are interested in credibility is not to say that they are concerned with a specific aspect or 'factor' bearing on knowledge. Credibility is not a factor in the sense in which, for traditional sociology of knowledge, 'class-allegiance' or 'religious affiliation' counted as 'social factors' contingently bearing upon knowledge – sometimes pertinent, sometimes not (e.g., Barber, 1952, p. 60). Credibility is the state achieved when knowledge-claims become knowledge, and the means for achieving credibility are the assemblage of means by which knowledge-claims become knowledge. From a pertinent point of view, credibility is the only topic for the sociologist of knowledge. As the philosophers might say, credibility has a transcendental

character for sociologists of knowledge: no credibility, no knowledge, no object of sociological study (Shapin, 1995a, pp. 257–8).

It might also be said, no credibility, no moral order. To give an account of what a community finds credible, and how it comes to find it credible, is tantamount to giving an account both of what that community is and how it experiences the world (Douglas, 1975, p. 238). So to say that sociologists of science should shift attention from truth to credibility is a way of orientating practitioners to the proper domain of inquiry, a way of discouraging them from arbitrarily limiting inquiry, and, finally, a way of reminding them of the potential pertinence of a range of social scientific and everyday resources that are available to give accounts of what people find credible.

No matter how highly valued or how technical the form of belief, the sociologist can usefully draw attention to the mundane means by which belief is made credible. In the ethnomethodological tradition, this was a maxim of method derived from the phenomenologists (especially Alfred Schutz) and from the later writings of Wittgenstein. Attention was to be directed to the 'behavior of seeking truth … the institutional and public character of truth, in contrast to the usual psychological and semantic descriptions that depict private disembodiments of that behavior.' For the sociologist, there is no other proper way of engaging with truth save through the study of what people collectively do: 'Truth resides in the rule-guided institutional procedures for conceding it.' In doing sociology, one should accept 'that there are no adequate grounds for establishing criteria of truth except the grounds that are employed to grant or concede it' (McHugh, 1970, pp. 320–1, 333–5). This sensibility strongly influenced the ethnographic study of science that began to emerge in the 1970s, especially with the work of Collins and co-workers (Collins, 1975, 1983, 1985/1992), but it also left a mark on historical studies of science concerned with how past communities established facticity, proof, and legitimate inference (e.g., Shapin, 1994; Dear, 1995; Porter, 1995; Poovey, 1998; Burke, 2000).

If, indeed, the practices for making and maintaining credible knowledge are co-extensive with the moral life of a community, then there are very few aspects of that life which do not potentially bear upon the credibility of belief. It follows that there can be no simple and coherent master-recipe for how credibility is to be achieved or model for understanding it. Much will depend upon the items of knowledge in question, the precise scenes in which the knowledge is assessed, and the state of transmitted background belief. Truth – like God and the devil – is in the details, and the sociologist wanting to understand why it is that a specific individual, or group of individuals, finds the special creation of species, or Darwinian evolution, credible may find it pertinent to consider a long list of mundane, and even some apparently trivial, features of cognition and social interaction (Shapin, 1999b, pp. 7–8, Lynch, 1993, pp. 278–88), while much work in the sociology of scientific knowledge during the 1970s and 1980s pointed to differences in collective goal-orientations (or social interests) as pertinent considerations in judgments of the credibility of scientific claims (e.g., Shapin, 1982, 1995b).

Accounting for Credibility: Economies of Trust

A large body of recent historical and sociological work has studied the means by which the veracity of scientific claims or the legitimacy of inference has been made persuasive. Because most natural know- ledge – that possessed by experts as well as by the laity – is held on the basis of trust, deferring to others whose knowledge is understood to be more direct or competent, even belief in matters of fact has to be actively secured: how persuasively to communicate the experience to be credited? how linguistically (and gesturally) to display one's entitlements to trustworthy knowledge? Studies of both historical and present-day episodes have drawn attention to the rhetorical constitution of authorial transparency, virtue, and intellectual entitlements; to the rhetorical invocation of allies leagued with the author and of the consequences of giving or withholding assent; and to the range of rhetorical means by which authors in general seek to assist the translation of individual claims into collectively credible knowledge (Latour, 1987; Shapin, 1984; 1994; Dear, 1995; Golinski, 1998, Chap. 4).

Recognizing the ineliminable role of trust in the credibility of knowledge is consequential for two diametrically opposed reasons. First, many situations present themselves – both within science and between scientific experts and the laity – in which the relative trustworthiness of sources is in doubt or is contested. The role of scientific expert testimony in courts of law, for example, is one important setting in which lay jurors are set the task of finding the signs of credibility in conflicting scientific accounts, and some studies emphasize the role of common-sense procedures in that task – monitoring testimony for manner and its sources for biasing interest (Brannigan and Lynch, 1987; Lynch and Jasanoff, 1998). Wynne's (1995) work on the public understandings of science, and specifically on the credibility of environmental radioactivity risk-assessments, stresses the complex array of considerations that bear upon lay attitudes towards which scientists, and which scientific pronouncements, are trustworthy. Epstein's (1996) study of the relations between AIDS researchers and AIDS activists is a richly detailed investigation of the grounds of trust in a situation where the very identity of laypersons and experts has been made problematic. Porter (1995) has asserted the crucial role of 'trust in numbers' in modern, complex, and highly differentiated societies, in which, as he argues, personal and familiar warrants for credibility are lacking or deemed inadequate. Jasanoff has examined how trust in expertise is secured in modern environmental science where conflicts over credibility are endemic (Jasanoff, 1992), and Hilgartner's (2000) work on a series of highly contested nutritional reports by the US National Academy of Sciences has drawn attention to the performative aspects of trust in modern expertise.

In the passages of modern 'extraordinary science' studied by Collins (1975), where the existence of specific physical phenomena and the competence of detecting instruments were simultaneously contested, members of a scientific 'core-set' reached out for a diverse array of contingent considerations to locate trustworthiness, and, therefore, to assess the credibility of technical claims: including the personal characteristics of claimants, the reputation of the institutions in which they worked, their allies, their track-records, etc. Historical studies of

scientific controversy (Shapin, 1994, esp. Chap. 6) have drawn attention to the imputed trustworthiness of the early modern gentleman in managing scientific controversy, in deciding the credibility of diverging claims, and even in deciding which controversies ought to be left undecided in favor of maintaining the interaction order.

In such lines of research, reposing trust in scientific claims and claimants appears as an actor's practical problem. Looking to see how and why actors reckon trustworthiness is a way of understanding how they deal with problematic credibility when experts disagree or when it is unclear who indeed is to count as an expert. There are plenty of such occasions in modern science, and especially in those sectors of science in which public participation in decision-making is mandated or pertinent. Is global warming a fact, and, if so, what is to be done about it? Who is to be believed about the risks of genetically modified foods and what policies should be framed for producing and labeling such foods?

Yet the second reason why trust is important in connection with scientific credibility is that the scientific community very often does speak – if not with one voice – then in a comparatively concerted way. Scientists in modern society are regarded as enormously trustworthy, and the credibility of what they concertedly deliver about the natural world is very great. Scientists are masters at trusting each other and they are masters at generating public trust in themselves. That is just another way of saying that consensual scientific knowledge is regarded in our society as the touchstone of truth. Scientific credibility may be an occasional problem, and a vitally important one, but it is also interesting to note how often in our culture the credibility of science does not manifest itself as problematic. Sociologists do not yet adequately understand how scientists achieve and maintain this trustworthiness and the resultant powers of professional credibility (Barnes, 1985, Chaps. 2–3), but the consequences of this trustworthiness for the social and intellectual order of modern society cannot easily be exaggerated (Bauman, 1992, p. 71; Shapin, 1995a). To understand the grounds of scientific credibility is to understand quite a lot about modern society. Scientific credibility is so blended into modern society's institutional life – its schools, universities, government, medicine, the military, and the media – that one cannot readily imagine credible science without the institutions which maintain and transmit it, nor credible institutions without the knowledge which gives them much of their legitimacy.

Abstract

Amos Tversky was a cognitive and mathematical psychologist who made fundamental contributions to research on judgment, decision making, and measurement. With his long-time collaborator, Daniel Kahneman, he advanced the heuristics-and-biases approach to judgment under certainty and the prospect theory approach to choice. For their joint work, Kahneman received the Nobel Prize in Economic Sciences (2002). A member of the US National Academy of Sciences, Tversky was also an author of the three-volume *Foundations of Measurement* and an influential theory of similarity judgments.

Amos Tversky was a cognitive and mathematical psychologist, whose research examined the foundations of human judgment and decision making. Much of that work described the strengths and weaknesses of the intuitive inferences that guide people as they struggle to cope with life's often diverse, complex, and subtle choices. Tversky's research typically characterized these inferences by comparing observed behavior with a formal model. Sometimes, the model was *descriptive*, predicting how people would behave if they followed basic psychological principles identified as relevant to the task. Sometimes, the model was *normative*, prescribing how ideal individuals would approach the task. Creating such models requires both mathematical and empirical expertise. Together with Daniel Kahneman, Tversky exercised that expertise in two singular accomplishments: the heuristics-and-biases approach to judgment under uncertainty and Prospect Theory for choices involving risk. The former assumes that people base their judgments on general rules of thumb that, although often useful, can produce predictable biases (e.g., exaggerating risks that the news media disproportionately report, making them unduly 'available' in memory). The latter proposes an alternative to utility theory, the normative standard for how decisions should be made, by elegantly integrating established psychological principles. With other collaborators, from diverse disciplines, Tversky developed theories of multi-attribute choice, similarity judgments, and the evaluation of evidence. His research methods ranged from pure mathematics to laboratory experiments to field studies in areas as diverse as medicine, law, and basketball. He coauthored the three-volume *Foundations of Measurement*.

Amos Tversky

Amos Tversky was born in Haifa, Israel, on 16 March 1937. His father was a veterinarian, and his mother a member of Israel's Parliament, the Knesset. He fought in Israel's 1956, 1967, and 1973 wars, and received its highest honor for bravery. He received his BA in psychology at the Hebrew University of Jerusalem in 1961. In 1965, he received his PhD from the University of Michigan's mathematical psychology program. He worked there with Clyde Coombs (his doctoral advisor), Ward Edwards, and David Krantz, among others. He returned to Jerusalem as a faculty member in 1967, moving to Stanford in 1978. A year at the Center for Advanced Study in the Behavioral Sciences provided Tversky and Kahneman with concentrated time to develop their approach to judgment under uncertainty, as did time spent at the Oregon Research Institute (later Decision Research).

Tversky died of melanoma, on 6 June 1996, in Stanford, California. At his death, he was Professor of Psychology at Stanford University, where he was also a Principal of its Center on Conflict and Negotiation. He held positions at Tel Aviv University, as Visiting Professor of Economics and Psychology, and as Permanent Fellow of the Sackler Institute of Advanced Studies. His wife, Barbara, is Professor Emerita of Psychology at Stanford and Professor of Psychology and Education at Teachers College, Columbia University, having studied spatial reasoning and communication. His three children are Oren, Tal, and Dona. He was known for his great energy, joy of life, and sense of humor.

Tversky made fundamental contributions to understanding human thought processes and to the mathematical foundations of the behavioral sciences. His work was distinguished by elegant formal models, tested in simple illustrative experiments. During much of his career, he collaborated with Daniel Kahneman, on studies of judgment and decision making under conditions of risk and uncertainty. He also collaborated with other scientists and scholars from psychology, economics, political science, law, statistics, philosophy, and mathematics. These projects, and the personal interactions surrounding them, helped to integrate these disciplines, despite pressures for specialization. Among his many honors were the Distinguished Scientific Contribution Award of the American Psychological Association, a MacArthur Fellowship, and honorary doctorates from Yale, Chicago, Göteborg (Sweden), and New York at Buffalo. He was a member of the US National Academy of Sciences, which served as one venue for pursuing his life-long commitment to encouraging peace and understanding. For their joint work, Kahneman received the 2002 Nobel Prize in Economic Sciences.

Axiomatic Theories of Choice

An early paper (Tversky, 1969) typifies his approach. Normative theories of choice provide rules that individuals should follow, in order to make effective decisions. The most prominent of these is utility theory, founded on a set of intuitively appealing axioms. It describes options in terms of attributes, or

features, that an individual might like or dislike. For example, when buying a car, the attributes might be price, size, styling, reliability, and comfort. According to utility theory, an individual should consider all relevant attributes, then rank the options according to their attractiveness, or *utility*. If the outcomes are uncertain, then they should be weighted by the probability of receiving them, and decision makers should choose the option with the greatest *expected utility*.

This ordering of the options should have the property of *transitivity*. A person who prefers Car A to Car B and Car B to Car C should also prefer Car A to Car C. Transitivity is an axiom or norm of *rational* decision making (hence the term *normative* analysis). When it describes decision makers' behavior, then they are better off because they are making better choices. So are scientists and policy makers. The former find it relatively easy to predict behavior, knowing that there is a stable overall ranking. The latter can create policy options (e.g., parks, housing, insurance schemes, transportation systems), knowing that the public will respond consistently. The appealing simplicity of the choice theory axioms has emboldened economists to make bold predictions about human behavior and strong prescriptions for public policies; if people are rational, then they can be expected to take full advantage of every choice offered to them.

Tversky, however, demonstrated systematic violations of transitivity, in studies using experimental tasks capturing key features of choices encountered in everyday life. Moreover, these studies did not merely show that utility theory described behavior imperfectly, making it possible to dismiss the violations as curiosities. Rather, Tversky showed that intransitivity arose from essential psychological processes, which he captured in a simple, but insightful model. Those processes reflected well-known limits to human information processing capacity, which make it impossible for people to discriminate fully among all possible options. As a result, unless they have the opportunity for trial-and-error learning, people can be, at best, *boundedly rational*, making orderly inferences about a subset of the full decision problem (Simon, 1957).

In the specific process that Tversky proposed, people simplify complex choices by initially comparing options on the most important attribute (e.g., car price), and then checking whether differences on the second most important attribute (e.g., reliability) are large enough to change their choice. Like many simplifying rules, or *heuristics*, this way of bounding a problem may be helpful in some situations, while producing problems in others. For example, imagine a customer making sequential comparisons between overlapping pairs of cars (A with B, B with C, C with D, and so on), arranged so that each new car is both cheaper and less reliable than the previous one. Looking just at the price would make each new option more attractive, while the reductions in reliability slowly mount up. At some point, though, if the first car were compared with the last car, a buyer might decide that reliability has gotten so low that the price reduction is too small to compensate for it. In that case, the first car would suddenly be preferred, despite having been initially rejected. Such intransitivity could, in principle, turn people into 'money pumps,' willing to pay something to move from one option to the next, but eventually going back to the first option and starting over again. As Tversky noted, car salespeople may try to exploit this cognitive limit by adding options (and costs) to a favored car. Unlike the experimenter, though, they hope to stop just short of the point where customers balk at the increased price and revert to the stripped-down model. Hanson and Kysar (1999), Posner (2010), and Thaler and Sunstein (2007) provide lively discussions of the implications of how to protect people from having their cognitive weaknesses exploited without denying them freedom of choice.

This early research captures a theme that recurs in Tversky's work, namely, that descriptively valid formal theories of human behavior should be assembled from psychologically plausible assumptions about what people actually do, rather than be derived from normatively postulated principles about what they should do (e.g., Tversky, 1967, 1972). Those assumptions gain plausibility if they are grounded in psychological research – which benefits, in turn, from being given formal expression and tested in decision making research. Thus, Tversky's demonstration of intransitivity builds on psychology's long tradition of studying 'context effects,' showing how sensitive choices, especially novel ones, can be to how options are presented. Choosing the relevant behavioral principles, from among the vast array identified by psychology, requires articulating the formal structure of choice situations. In some cases, Tversky did that by adapting existing mathematical approaches. Other cases prompted new mathematics, much of it appearing in three landmark volumes (Krantz et al., 1971/1989/1990). The study of alternative choice rules for multiattribute options has become a cornerstone of *conjoint measurement*, a family of procedures used widely in applied research (e.g., marketing multiattribute consumer products).

Prospect Theory

These strands of formal and empirical research came together in Kahneman and Tversky's (1979) 'prospect theory.' Published in a leading economics journal, it offered an alternative to utility theory, the core of that discipline. It depicts individuals as thinking about their choices in orderly, sensible ways. However, the rules that they follow differ from those prescribed by the axioms of utility theory, in ways that produce systematic violations. It holds that people are both sensitive to features of choices with no representation in utility theory and insensitive to ones in the theory. Prospect theory promises greater descriptive validity than utility, but at the price of abandoning economists' normative aspirations. Markets cannot be trusted to operate efficiently, if people may not make decisions in their own best interests.

Superficially, prospect theory resembles utility theory. 'Prospects' (i.e., options) are represented as sets of possible outcomes. The *value* (rather than the 'utility') of a prospect is the sum of the values assigned to each outcome, weighted by its chances of happening. However, the components of this evaluation differ from their utility theory analogs in ways that made them more realistic psychologically (Tversky and Kahneman, 1991):

1. Outcomes are evaluated relative to a *reference point*, rather than with respect to an individual's *net asset position* (or overall worth). The status quo is a natural reference point;

people focused on it ask how much better or worse off a choice will make them. However, the reference point could also be another salient value, as when people evaluate a pay raise relative to what they expected to get (or what others got), rather than relative to their current salary. This feature of prospect theory captures the psychological principle that people are sensitive to changes (Helson, 1964), unlike economic analyses, which assume that people always count their blessing, looking at any outcome in terms of all that they have in the world.

2. People care less about any given absolute difference (e.g., X dollars, Y minutes) as the overall change increases, for both gains and losses. Utility theory also assumes that people care less about a fixed gain as they have greater wealth. However, it makes the opposite assumption for losses, namely, that a given loss is increasingly painful as total losses mount up. For example, utility theory attributes insurance buying to people being so averse to large possible losses that they willingly incur small certain ones (premiums). This feature of prospect theory captures the psychological principle that it takes a larger difference to be noticed when the overall change is larger – whatever the direction of that change.
3. Before being combined with value judgments, the probabilities of the outcomes are multiplied by a *probability weighting function*. It holds that people pay particular attention to sure things, while being relatively indifferent to probability differences in the middle range (e.g., the difference between 0.35 and 0.45 matters less than that between 0.90 and 1.00). This feature of prospect theory reflects the observation that tangible outcomes mean more than intangible probabilities.

As combined in the theory, these principles (along with some others) predict (among other things) a form of context effect called *framing*, achieved by shifting the reference point. Continuing an earlier example, the same raise can seem like a gain when compared with current wages, but a loss when compared with the expectation of a larger one. In one widely used demonstration, an emergency medical intervention that could save 200 of 600 possible lives is more attractive when described in terms of the 200 lives saved than the 400 lives lost. Such changes can reverse choices, in ways that have no reflection in utility theory (which has no such reference point), hence are irrational (in its terms).

Prospect theory's challenge to utility theory evoked vigorous responses. Some suggested radical methodological skepticism, with partisans attacking any feature of the research that could, conceivably, have artifactually contributed to evidence supporting the theory. Amidst these ad hoc claims, though, were ones that raised fundamental questions, prompted by the power of prospect theory's results. One concerns the role of financial incentives in research, where economics and psychology have conflicting norms. Economists typically believe that people pay little attention to tasks without incentives, while calculating the angles with tasks that have them (e.g., lying about their beliefs if these is some advantage to doing so). In contrast, psychologists typically view all behavior as 'real,' with researchers facing the challenge of deciding (or controlling) how individuals construe their tasks. In one summary, Camerer and Hogarth (1999) find varied impacts of monetary rewards on decision making performance, partially depending on whether people have the skills needed to respond to incentives.

At the other extreme lie economists who accept the validity of prospect theory's results and use them to reflect on their science. Some have examined its implications for the axiomatic basis of utility theory, either refining those axioms to fit the data better or replacing them with different normative principles. Some have examined the practical implications of nonrational behavior, spurring new fields like behavioral finance, which questions efficient market theories, and approaches like libertarian paternalism (Thaler and Sunstein, 2007), which advocates structuring choices so that people are more likely to do what experts hold to be best for them (e.g., saving more for retirement).

Another research direction that prospect theory has propelled focuses on understanding the sort of inconsistent preferences revealed in framing effects. One general approach holds that preferences for specific prospects are often inferred (or *constructed* or *articulated*) from more general, basic values. Contextual cues, like reference points, shape that process, producing inconsistent preferences. Predicting those preferences requires knowing those cues. Informing those preferences requires bringing potentially relevant perspectives to decision makers' attention, so that they can come to know what they want (Fischhoff and Kadvany, 2011; Lichtenstein and Slovic, 2006).

Judgment under Uncertainty: Heuristics and Biases

For economists and psychologists concerned with decision making, values are a matter of personal preference. As a result, showing them to be suboptimal means demonstrating inconsistencies. With beliefs, suboptimality can be established by comparing judgments to one another (looking for inconsistency) or to an accepted external standard (looking for error). In their first published collaboration, Tversky and Kahneman (1971) adopted the latter strategy, finding that mathematically sophisticated scientists systematically misjudged the statistical power of research designs. Although these scientists knew how to calculate power, when forced to rely on intuition, they exaggerated the chances of observing anticipated results, acting as though the law of large numbers applied to small samples as well.

Tversky and Kahneman (1974) proposed that these judgments arose from relying on the *representativeness* heuristic, whereby an event appears likely to the extent that it captures (or 'represents') the salient features of the situation that might produce it. As a result, people who rely on representativeness will neglect factors without salient roles, however relevant they should be. Sample size is one natural candidate for such neglect. If a situation can produce an event, why should it matter how large a sample is observed? A second normatively relevant factor with no role in representativeness is the relative frequency of past observations. People should rely on such *base-rate* (or a priori) information unless there is strongly diagnostic *individuating* information, showing why a specific case is different from the norm. (Medical students are

sometimes told, 'When you hear hoofbeats, think horses, not zebras' – unless in Africa or at the zoo.) However, studies find that even flimsy case-specific evidence can override knowledge of what is generally true. It is natural to think about how well someone fits the image of an engineer (or how much a lump looks like a tumor). It is not so natural (or easy) to combine that vision or theory with a statistical summary of the frequency of engineers (or tumors) in the population (Gilovich et al., 2002; Kahneman et al., 1982).

Analogous reasoning leads to predicting that people who rely on representativeness will underestimate regression to the mean (because error is not represented in the process producing an observation) and exaggerate the predictability of random sequences (because their properties should be represented even in small samples). The latter was demonstrated in studies showing an illusory belief in being able to identify streaks in basketball free-throw shooting. Both collegiate and professional players (and fans) interpreted patches of random sequences as reflecting transient 'hot hands' (Gilovich and Tversky, 1985).

A second heuristic for judgment under uncertainty is *availability*, whereby an event seems probable to the extent that examples easily come to mind. Like other heuristics, it has some validity, when unfamiliar events are unlikely, and draws on natural ways of thinking (people appear to keep mental records of how often they have seen events without even realizing it). However, availability can also predictably lead people astray, as when the news media report some risks much more often than others (e.g., homicide vs asthma) and people cannot correct for the extent to which appearances are deceiving (Slovic, 1987). A third heuristic, also with historical roots in psychology (Poulton, 1994), is *anchoring and adjustment*. Users estimate uncertain quantities (e.g., temperatures, stock prices, building heights) by selecting a salient value (the 'anchor'), then adjusting from there, based on whatever other concerns come to mind. Typically, that adjustment is insufficient, leaving people 'anchored' in the initial value. If the anchor is far from the correct one, then the resulting estimate will be, too.

Just as it drew on basic psychological research, the heuristics-and-biases program also stimulated new directions in it. Tversky and Koehler (1994) subsequently formalized the relationship between evaluations of evidence and probability judgments in 'support theory,' organized around how people weigh the reasons for and against a hypothesis. Like its predecessors, support theory predicts the conditions under which simple, intuitive thought processes lead to sound judgments and poor ones. Tversky's (1977) theory of similarity judgments uses measure-theoretic concepts to predict judgments of representativeness (among things). The theory explains, for example, why people are more likely to say that a son looks just like his father, rather than vice versa (unless they know the son much better). Shafer and Tversky (1985) produced a general account for when judgmental biases raise questions regarding the validity of the normative standard against which judgments are compared.

Amos Tversky's work continues to be profoundly influential, long after his death, as scientists examine their implications and the scientific community hopes for other individuals with his rare combination of intellectual skills, insight, and insistence on 'getting it right.'

Twin Studies and Epigenetics

Abstract

Epigenetics is the study of chemical and cellular modifications to DNA and chromatin, which alters the expression of genes without altering the underlying DNA sequence. The state of epigenetic elements can change over time and can have a heritable component, but can also be modified by internal and external environmental factors. Therefore, epigenetic phenotype analyses should take into account the dynamic nature of epigenetic mechanisms, and control for potential confounders, such as age and genetic factors. Twin studies provide valuable information about the genetic as well as the epigenetic epidemiology of complex traits and diseases. Such unique studies can explore the relationship between genetic, environmental, and random factors and their interactions with, for example, sex, age, and lifestyle factors underlying a phenotype of interest. Using twins provides a powerful model to help us unravel the multifactorial components of complex diseases and traits.

Epigenetic Mechanisms

The term 'Epigenetics' combines the word 'epi' (Greek: επί – over, above, outer) and 'genetics,' and was first proposed by Waddington (1942) to describe the epigenetic landscape of gene regulation during development. More recently, epigenetics has been defined as the study of chemical and cellular events, such as the modulation of gene expression or cellular phenotypes, caused by mechanisms other than changes produced by the underlying genetic architecture (Holliday, 1994). External and internal environments can stimulate these changes, and the changes could be either persistent or transient. Both persistent and transient epigenetic changes can have lasting physiological impact.

Various studies (cf **Table 1**) have mapped epigenetic elements and annotated the human genome in a way that facilitates identification of potential functional gene sequences. Such general studies underline how epigenetic mechanisms in mammals play an important role in gene expression, regulation, and development and therefore in disease (Murr, 2010). One of the main findings is that epigenetic variants across different epigenetic mechanisms tend to co-occur in specific genomic regions. These epigenetic elements could be either so-called *cis*-regulatory elements, which work through intramolecular interactions (the epigenetic element is in the same chromosomal region as the regulated gene), *trans*-regulatory elements, which work through intermolecular interaction. **Table 2** and **Figure 1** present a general description of epigenetic elements.

DNA methylation (Guibert and Weber, 2013) in mammals is the addition of a methyl group to the cytosine base of the DNA structure, and is the most abundant, stable, easiest to measure, and well-studied epigenetic mechanism in humans. Consequently, the following sections focus mainly on the current knowledge about this epigenetic marker. DNA methylation plays a role in gene regulation, chromosomal stability and X-chromosome inactivation, and parental imprinting. Genetic imprinting is a DNA methylation process by which alleles can be expressed in a parent-of-origin-specific manner, while X-chromosome inactivation (also called lyonization) is a random phenomenon in each cell that inactivates one of the two copies of the X-chromosome present in female mammals. The two latter processes are the first DNA methylation phenomena studied (cf Table 4 (Supplementary Data)). In mammals, DNA methylation occurs on the 5-carbon position of cytosine predominantly in the context of CpGs dinucleotides. CpG-rich regions, called 'CpG islands' (CGIs) which are

Figure 1 Epigenome maps: the figure represents the different epigenetic mechanisms occurring at different levels in the cell and working together (left to right): at the level of conformation of DNA sequence – such as chromatin structure or attachment to the nuclear matrix; at the chromatin level – such as histone modification; at the DNA sequence level – such as Gene expression; at the level of interaction with other epigenetic factors – such as microRNA and transcription-factor binding; or at the DNA sequence level – such as DNA methylation.

predominantly hypomethylated. CpG islands tend to colocalize with gene promoters, gene-bodies, and regulatory regions. *De novo* methylation in a promoter region usually switches the gene from active to inactive (Klose and Bird, 2006). At other CpGs sites outside promoters, the role played by methylations is less clear as is methylation in non-CpGs sites.

Twins

Twins represent a particular type of full-sibling. They can share part or all of their genomes, their intra-utero environments, and early lifetime events and experiences.

There are different types of twins depending on the degree of genomic identity, called zygosity. The two types of twins are: monozygotic ('identical') (MZ), who share almost 100% of their genome and share most of their *in utero* and early life environment, and dizygotic ('fraternal') (DZ), who share most of their *in utero* and early life environment but only around 50% of the segregation of their genome, and who can be either same-sex or opposite sex pairs. DZ twins come from two different eggs independently fertilized by two sperms at the same time, while MZ twins share the same egg (the same proportion of maternal and paternal genomes). Male–female dizygotic twins are the most common type of dizygotic twins, whereas it is slightly more common to have female–female monozygotic twins than male–male monozygotic twins, due to mortality rates.

Nature generates more diversity in twins than just zygosity (cf **Figure 2(a)**). For instance, the degree and delay of separation between MZ twins *in utero* defines different types of identical twins; or the adoption of twins in different families plays a role on the proportion of shared environment and individual environment. Moreover, random genetic mutations may occur at any time during the development of the embryo and continue to arise during lifetime, increasing the genetic difference between individuals with a frequency of roughly 0.1–100 per genome per sexual generation but currently indistinguishable from 1/300 per cell division per effective genome (Drake et al., 1998).

Monozygotic twins may not be exactly genetically identical (100%) and can have some minor mutational differences (single nucleotide polymorphism – SNP – and small insertion/deletion region – InDels) (Li et al., 2014; Weber-Lehmann et al., 2014). Recently, Li et al. (2014) estimated that somatic mutation (mutation happens in any cell other than a gamete, germ cell, gametocyte, or undifferentiated stem cell) in monozygotic twin pairs has a frequency of 1.2×10^{-7} per base pair. MZ twins may also differ in copy number variation but the extent of these differences remains unclear (Bruder et al., 2008). Mutations that distinguish MZ twins must occur after the morula splits (about four to five days after fertilization), or just beforehand in a confined area of embryo. These mutations can be present in germ cells but not in other tissues and vice versa or in both germline and somatic cells. Recently, researchers (Weber-Lehmann et al., 2014) showed that they could distinguish identical twins based on single nucleotide differences in their genomes in a forensic case that involved monozygotic twins.

Figure 2 Diversity of twins caused by genetic and environmental factors. (a) Different types of twins and their phenotypic difference in early life are determined by the timing of the egg split. The latter plays on the number of amniotic and chorionic (placenta) sacs, consequently on the intrauterine shared environment. Almost one out of three twins is monozygotic twin, who is partitioned into four different groups. The timing of the split and the percentage of each group were obtained from Hogenson, T.L., 2013. Epigenetics as the underlying mechanism for monozygotic twin discordance. Medical Epigenetics 1. The first rectangle on the right hand side gives the percentage of shared genomic segregation, namely almost 100% of genomic segregation for MZ twins and almost 50% for DZ twins. The next double rectangles with blurred edge indicate the raising influence of environmental factors during embryonic development (from top to bottom). There may be a slight decrease influence of environmental factors between dichorionic-diamniotic MZ twins and dichorionic-diamniotic 'fused' DZ twins, because there is fusion between the blastocysts of DZ twin pairs in the early stage. Furthermore, the proportion of environmental factors between monochorionic MZ twins and dichorionic MZ twins, may be influenced by twin-to-twin transfusion syndrome (TTTS) or other phenomena (Kaminsky, Z.A., Tang, T., Wang, S.C., Ptak, C., Oh, G.H., Wong, A.H., Feldcamp, L.A., Virtanen, C., Halfvarson, J., Tysk, C., McRae, A.F., Visscher, P.M., Montgomery, G.W., Gottesman, I.I., Martin, N.G., Petronis, A., 2009. DNA methylation profiles in monozygotic and dizygotic twins. Nature Genetics 41(2) 240–245; Gordon, L., Joo, J.E., Powell, J.E., Ollikainen, M., Novakovic, B., Li, X., Andronikos, R., Cruickshank, M.N., Conneely, K.N., Smith, A.K., Alisch, R.S., Morley, R., Visscher, P.M., Craig, J.M., Saffery, R., 2012. Neonatal DNA methylation profile in human twins is specified by a complex interplay between intrauterine environmental and genetic factors, subject to tissue-specific influence. Genome Research 22 (8) 1395–1406). The combination and the interaction of genetic effects and environmental effects define the phenotypic variation between twins (described at the top of the figure). The last rectangle shows a potential distribution between genetic effect (blue part) and environmental and stochastic effect (red part) on phenotype at time T and cell type given just after birth. This proportion of different variants (genetic, environment, stochastic) playing on phenotype changes over time and site. (b) The draw shows how external environmental factors affecting the mother plays, also and many more, a role on the epigenetic modifications of the fetus and its given reproductive cells during the development stage. The panel shows how external environmental factors play a role on the epigenetic modifications of the mother, but also potentially on the epigenetic modifications of the fetus and its reproductive cells during the development stage.

Epigenetic States Change over Time and Site

From a general perspective, a multicellular eukaryotic organism, including human organisms, starts from one unique cell, which splits into multiple differentiated cells. A set of epigenetic markers, imprinted genes, and in females' X-chromosome inactivation, is found in all cells of a given organism. These are typically the outcome of epigenetic markers defined in embryogenesis. Only around 100 imprinted genes out of 23 000 are currently known to exist, and this may be because of a reprogramming step that erases most epigenetic signals from parental gametes and also from the zygote. This step ensures the totipotency of early embryonic cells (the ability of a single cell to divide and produce all of the differentiated cells in an organism). Although all cells have almost the same genetic information, they can differ significantly due to epigenetic mechanisms. Moreover, contrary to genetic sequence, epigenetic elements change over time at much higher frequency. Indeed, epigenetic modification plays an important role in regulating gene expression, developmental stages and in tissue differentiation (Colaneri et al., 2013), and therefore in cellular and metabolic memory.

Locus-Specific Effects

Epigenetic variation occurs and develops at different rates across different genomic regions, called also loci. These events depend on three factors, which can act independently or in combination: stochastic drift of epigenetic states, genetic variation, and environmental factors. Martino et al. (2013) observed that in singletons as well as twins, 30% of their assayed CpGs undergo dynamic methylation during the first 18 months of life and some of these methylation events are independent of constrained developmental programs. Moreover, the pattern and the variation of DNA methylation seem to differ according to the annotated function of genetic regions (CpG islands, CpG islands shores, and coding sequence) (Davies et al., 2012). An increase in the variation of DNA methylation over time is observed in annotated genomic regions. By contrast, a significant decrease of the variation of DNA methylation is shown in intragenic regions, enhancers, and low-density CpG promoters (Martino et al., 2013). Epigenetic mechanisms can also give rise to comethylation of several contiguous CpGs in the same direction, and in some cases striking interindividual variability, forming variably methylated regions (VMRs) (Feinberg and Irizarry, 2010).

Cell-Specific and Tissue-Specific Effects

Epigenetics play a key role in the cell cycle, as well as, in cellular and tissue-level differentiation (Khavari et al., 2010). In order to ensure the progression of the cell cycle, epigenetic mechanisms vary across cell cycle phases in governing genome accessibility, and consequently, the expression of individual genes. These variations are shortlived and are not inherited. However, during cellular division, the epigenetic patterns of cell and tissue type are transmitted to daughter cells to maintain tissue integrity. During the mitotic phase and after cellular differentiation, cells reprogram themselves to produce new required functional cell-type.

Data from several sources have identified differences in epigenetic modifications between cells, cell types, and tissues (Davies et al., 2012; Wu et al., 2011; Zhang et al., 2013). Genome-wide DNA methylation patterns are highly tissue-specific, between the tissues of brain and blood for instance, or between the tissues of functionally distinct areas of brain (Davies et al., 2012). Additionally, Wu et al. (2011) observed that DNA methylation differs between different blood cell types. Interestingly, a greater genome-wide epigenetic variation was observed between different tissues of the same individual than between the same cell type of different, unrelated individuals (Eckhardt et al., 2006). This demonstrates clearly a significant tissue-specific effect (Eckhardt et al., 2006). In the epigenetic study of phenotypes, the epigenetic state associated with the complex trait may be a tissue-shared or tissue-specific effect, and therefore the selection of studied tissue or cell type may have an impact on the findings. Thus, the tissue or cell type selected for epigenetic phenotype analysis should be the most appropriate to the complex trait or studied disease.

Unfortunately the most appropriate cell type or tissue for omic studies (for example, epigenomic or transcriptomic studies) of specific complex traits or diseases is not always easily accessible, abundant, or even known. There are clear DNA methylation differences across tissues at cell-type and tissue-specific sites. However, a number of recent studies (Davies et al., 2012; Shenker et al., 2013) suggest that whole blood could be a useful surrogate for less readily available tissues (e.g., brain or lung, in pre-mortem individuals) for molecular biomarker studies for epigenetic modifications. The same cannot be said for gene expression (Witt et al., 2013). Studies comparing the methylation alterations of brain and blood concluded that whole blood might also be a proxy for brain tissue (Davies et al., 2012; Shenker et al., 2013). Within an individual, Davies et al. (2012) have recently shown that a significant correlation ($R^2 > 0.66$) was observed between DNA methylations in whole blood and in tissue derived from brain. The epigenetic patterns observed in blood may therefore be a relevant proxy, depending on the particular genomic region for defining biomarkers of environmental factors that are difficult to quantify in epidemiological studies.

Sex and Gender Effects

DNA methylations and histone modifications differ between sperm and oocyte (Duffié and Bourc'his, 2013). The differences are found in imprinted genes. The majority of imprinted genes come from maternal imprinting control regions (ICRs), which correlate with CpG-rich promoters, while paternal ICR occur more frequently in CpG-poor, intergenetic regions. Apart from X-chromosomal inactivation, which occurs in cells from female individuals after fertilization, the effect of sex and gender on DNA methylation is controversial. A gender-specific effect was detected for some genes in autosomal chromosomes in twins and healthy controls (Boks et al., 2009) in whole blood, whereas some disease studies demonstrated no clear 'gender effect' (Bell et al., 2011) in lymphoblastoid cell lines. Consequently, until we know more, when studying complex traits and diseases affected by gender, it is preferable to use unrelated individuals or twin pairs of the same gender.

Aging Effects

From epigenetic studies of twins and unrelated individuals (for example, Martino et al., 2013; Bell et al., 2012; Rakyan et al., 2010; Teschendorff et al., 2010; Fraga et al., 2005), it was found that aging strongly influences epigenetic markers. A significant discordance is observed in MZ twins in their early life and this discordance and variation in methylation increases with age. Fraga et al. (2005) observed an increase in epigenetic differences between MZ twins with age. In selected CpGs sites they observed a higher DNA hypomethylation, and a higher histone H3 and H4 hyperacetylation (usually associated with transcriptional activation) in the older sibling. Martino et al. (2013) reported that epigenetic differences already exist in MZ twins at birth and increase over their lifetimes in response to stochastic and environmental factors. Moreover, certain DNA methylation sites have been identified as biomarkers of aging (for example, Martino et al., 2013; Bell et al., 2012; Rakyan et al., 2010; Teschendorff et al., 2010; Fraga et al., 2005); and as expected very few of these are related to genetic variations using methylation quantitative trait loci (meQTL) (Bell et al., 2012, Tsai et al., 2012). However, it is possible that the aging methylation effects that have been reported in whole blood are an artifact of increasing blood cell type variability with age (Jaffe and Irizarry, 2014), although several of the aging methylation studies either controlled for whole blood cell type variability (Bell et al., 2012) or the studied specific blood cell subtypes (Rakyan et al., 2010). High levels of confounding between age-related variability and cellular composition as detected by DNA methylation as specific CpG sites were detected in some of the data of previous papers reporting age-related changes of DNA methylation profiles (Jaffe and Irizarry, 2014). Thus, future epigenetic studies of aging should take into account cell composition. Horvath (2013) found that 353 CpG sites together act as an 'ageing clock' in terms of chromatin states, cell states, and tissue variance, and can accurately predict the age of an individual, independent of many tissue types. In addition to DNA methylation markers of aging, other epigenetic marks can also associate with age, such as microRNAs. Multiple miRNAs have been reported to be deregulated during cellular senescence, aging, and disease (Wolfson et al., 2008).

Epigenetic: Genetic, Environmental, and Stochastic Factors

Epigenetic elements differ among related and unrelated individuals and among species; they also change over time, depending on locus. We examine the epigenetic markers that are heritable and the mechanisms that maintain this inheritance.

The Heritability of Epigenetic Modifications

In general, the heritability of a phenotypic trait is defined as the proportion of the total phenotypic variation of this trait that is explained by genetic variation alone. The phenotypic variation of a trait (P) can be partitioned into contributions from latent genetic (G) and environmental (E) factors, and gene–environment interactions (G×E). To a lesser extent, there is the stochastic influence inside each cell (S), such that $V_P = V_G + V_E + V_S + V_{GxE}$. The genetic variation can be due to additive genetic variance (V_A) as well as nonadditive genetic variance that can be related to interactions between alleles at the same locus (dominance, V_D) and/or at different loci (epistasis, V_I): $V_G = V_A + V_D + V_I$. The environmental influence can be split into the environment shared by the study group, for example shared by family members ('the common environment,' V_C), the environment specific to each individual, but common to repeated measures ('the unique environment,' V_U), and the environmental variance that is not explained by other parameters (for example, error variance inside repeat measures, $V\varepsilon$): $V_E = V_C + V_U + V\varepsilon$. Thus, phenotypic variation can be expressed as $V_P = V_A + V_D + V_I + V_S + V_C + V_U + V_{G\times E} + V\varepsilon$. Two estimators of heritability are commonly defined. First, broad-sense heritability (H^2) takes into account total genetic variation (V_G); thus $H^2 = V_G/V_P$. Second, narrow-sense heritability (h^2) takes into account only the additive genetic variation (V_A); thus $h^2 = V_A/V_P$.

Inheritance of epigenetic states may be studied during both mitosis and meiosis. The latter could potentially lead to trans-generational epigenetic inheritance, which is currently a highly controversial topic, due to confusion of the term with inter-generational exposure (Daxinger and Whitelaw, 2010). For example, if environmental exposures occur during pregnancy or during spermatogenesis (Schmidt, 2013), up to three generations (two for paternal environmental exposures) can be affected by the same environmental factors without being dependent on meiotic inheritance mechanisms (cf **Figure 2(b)**). It is therefore important to distinguish between experiments that explicitly test for epigenetic meiotic heritability, and cases of multigenerational exposure. Only epigenetic markers transmitted across four or more generations that exclude other potential confounders such as maternal effects, may be reported as heritable. Rare reports of trans-generational epigenetic inheritance exist (Stern et al., 2012), but the precise mechanisms underlying these effects remain unknown and need to be reconciled with extensive epigenetic reprogramming during embryogenesis.

Heritability of epigenetic states during cellular division is studied where the epigenetic state at each position is the phenotype. Heijmans et al. (2007) performed one of the first studies of epigenetic heritability using twins, in the *IGF2/H19* locus with 196 adolescent and 176 middle-aged twins. They estimated heritability to be 20–70% for the *H19* DMR twins and 57–97% for the *IGF2* DMR twins; and showed that a proportion of the heritabilities is explained by SNPs in cis (the single nucleotide polymorphism is in the same chromosomal region as the epigenetic element studied). They concluded that the IGF2/H19 locus is predominantly driven by heritable factors. Kaminsky et al. (2009) explored three different tissue types: white blood cells (WBC), buccal epithelial cells, and gut biopsies of 114 MZ and WBC and buccal epithelial cells of 80 DZ, using a microarray assaying 12K CpG promoter regions. They observed that intraclass correlation coefficient (ICC) profiles were more similar across tissues of the same individual compared to unrelated individuals and that both CGIs and promoters were less epigenetically variable in WBC and gut cells. The heritability of DNA methylation in

buccal epithelial cells was slightly higher than that in WBC, (mean $ICC_{MZ} - ICC_{DZ} = 0.15 \pm 0.0039$, $p = 1.2 \times 10^{-294}$ compared to mean $ICC_{MZ} - ICC_{DZ} = 0.0073 \pm 0.0034$, $p = 0.044$). Surprisingly, Kaminsky et al. (2009) and recently Gordon et al. (2012) observed that DNA methylation profiles in different tissues (buccal cells for Kaminsky et al. (2009) and cord blood mononuclear cells and human umbilical vascular endothelial cells for Gordon et al. (2012)) are more discordant within monochorionic MZ twins than within dichorionic MZ twins. The explanation of this observation remains unclear and this outcome needs to be validated in a larger sample size. Recently, Grundberg et al. (2013) performed a much larger study in adipose tissue from 648 twins with the Illumina 450K platform (a microarray platform that measures methylation levels at 485 000 CpG sites genome-wide) located predominantly in gene-based regions, but also in some intergenic regions – estimating heritability, h^2, of methylation sites genome-wide at 0.19. But this estimation increased to 0.34 in selecting only the top 10% of variable sites (TVS), enriched in gene bodies and intergenic regions and depleted of promoter regions and CGIs. In concordance with TVS, highly heritable sites ($h^2 > 0.5$) were enriched in hypermethylation, enriched for gene bodies and intergenic regions, and depleted of promoter regions and CGIs, which tended to be hypomethylated.

As discussed previously, aging effects act on epigenetic modifications (Bell et al., 2012; Tsai et al., 2012) or cell composition (Jaffe and Irizarry, 2014); heritabilities can also change over time and site. Based on an original idea by Slatkin (2009), epigenetic events could partly explain the missing causality of complex diseases or traits, but not the missing heritability of complex diseases. Currently, many questions about the extent and mechanisms of such inheritance remain unanswered.

Genetic Effects

Many studies on the heritability of DNA methylation, such as Heijmans et al. (2007), Kaminsky et al. (2009), and Grundberg et al. (2013), explored whether the variation of DNA methylation is related directly to underlying genetic variation. Heijmans et al. (2007) showed that a genetic mutation directly at a CpG site itself changes the interindividual normal distribution of methylation variation to that of a binominal distribution. Using quantitative trait-mapping methods, CpG meQTLs (Bell et al., 2011) were identified in lymphoblastoid cell lines from 77 HapMap Yoruba individuals. The majority of meQTLs were observed in cis and SNPs that associated with gene expression levels overlapped meQTLs, providing evidence for shared mechanisms in a set of genes. Recently, Grundberg et al. (2013) replicated this finding in adipose tissue on larger set of data. Additionally, they detected that 28.5% of CpG sites are associated with a common sequence variant among filtered probes (probes having no known SNPs, InDels, structural variations (SVs), or CNVs both within the probe and at the CpG site). These CpG sites associated with at least one common sequence variant have higher h^2 (0.44); and, on average in TVSs, 15% of common variants explained more than 50% of the methylation heritability per site. Studying such epigenetic modifications under the control of genetic variations may highlight a genetic sequence, environment correlation, or interaction. Consequently, certain epigenetic states may be inherited at the same time as genetic variations.

Fraser et al. (2012) identified and compared meQTLs between the HapMap YRI and CEU samples. They found that 30% of the studied CpG sites differed between populations, but with a small magnitude in population-level methylation differences (approximately 4% of CpG sites having only in average over 10% of population-level methylation difference). Additionally, a wide range of within-population variability in the methylation of individual CpG sites was observed. Population stratification investigating the effect of a genetic factor on disease in epidemiologic studies (Wacholder et al., 2000) could be a manifestation of confounding in epigenetic epidemiologic studies. However, one-third of population-specific DNA methylation variations were not explained directly by genetic variations defined by meQTL methodology (Heyn et al., 2013a). Thus, the methylation divergence between and within populations may be due to a combination of differences in allele frequencies and complex epistasis or gene × environment interactions. Heyn et al. (2013a) concluded that epigenetic mechanisms might help to tune the human genome in response to environmental factors and to explain natural human phenotypic variation.

Liu et al. (2014) defined GeMes as noncontiguous sets of correlated CpGs under the genetic control of one or more methylation quantitative trait loci. They observed that CpGs belonging to same differentially methylated regions (DMRs) cluster together in their variation and are associated to environmental factors such as smoking. Simultaneously, some of these noncontiguous methylation clusters are correlated with each other and can be genetically driven. This pattern is similar to that of linkage disequilibrium (LD) correlation in genetic SNP variation, but for over a much shorter distance, less than 500 bp compared to roughly 3 kb. The mechanisms by which epigenetic variations and genetic variations are related to population variations remain unclear.

Environmental Effects

Epigenetic states can be influenced by the environment, either short or long-lived; and some are transmitted to daughter cells (Cortessis et al., 2012). Environmental factors can be either exogenous, such as diet, medication, lifestyle, and behaviors or endogenous, such as inflammation and hormonal change. Interestingly, Grundberg et al. (2013) observed that 8638 CpG sites of adipose tissue influenced by 30% shared environmental factors are significantly associated with metabolic functions. Overall shared environmental factors contribute to 0.2% of methylation variation of all sites and 2% of TVS, while non-shared environmental and stochastic factors account for 80.8% and 44% respectively (Grundberg et al., 2013).

Tobacco smoke provides the best reproducible example of environmental epigenetics. The first study, using the sparse Illumina 27K platform (Breitling et al., 2011) – a microarray platform that measures methylation levels at about 27 000 CpG sites, which are located mainly in the promoters of RefSeq genes involved in cancer – found a relationship between tobacco smoke and altered DNA methylation at a single locus, the coagulation factor II (thrombin) receptor-like 3 (F2RL3) gene.

Wan et al. (2012) validated the reported loci associated with cigarette smoking and identified a novel locus, G-protein-coupled receptor 15 (GPR15). Using the Illumina 450k array, two studies, one in peripheral blood and lung tissue (Shenker et al., 2013) and the other in whole blood (Zeilinger et al., 2013) replicated the findings and defined a new set of biomarkers and concluded that upon cessation of smoking the DNA methylation state generally reverts back to an intermediate level compared to nonsmokers. Looking at fetal exposure of maternal smoking during pregnancy (PTS), a reduction in DNA methylation of repetitive elements like satellite repeats (e.g., Sat2) or an intra-genetic region of the aryl hydrocarbon receptor repressor gene (AHRR) persisted into adulthood (Joubert et al., 2014; Flom et al., 2011). Similarly, studies on epigenetic changes in rats receiving cigarette smoke concluded that this decrease of DNA methylation could be found also in F2 offspring of F1 offspring exposed during pregnancy.

These studies highlight four main types of relationship between epigenetic and environmental factors: (1) even after stopping exposure of an environmental factor, the persistence of the epigenetic modification can be detected in adulthood, (2) epigenetic states of offspring can be impacted by parental behaviors, and (3) modification or reversal of epigenetic states can take place during adulthood; (4) effects can be seen across tissues.

Stochastic Effects

The variability of epigenetic modifications that is not attributed to environment, measurement error, or genetic factors may be attributed to stochastic ('random') effects. For example, in early life MZ twins already have some differences at the level of DNA methylation, which can potentially be explained by differences their intrauterine environment (Martino et al., 2013). However, when Ushijima et al. (2003) worked on the transmission of DNA methylation between cells during mitosis, they showed that the fidelity in this transmission is not perfect and that there is a larger error rate for epigenetic states than for DNA sequences. The phenomenon of stochastic epigenetic instability, or stochastic drift, can accumulate over time and across cells. Consequently, a phenotype is generated by a combination of stochastic effects, environmental factors, and genetic impacts. The majority of studies found no distinction between stochastic effect and nonshared environment (confounding), and twin studies cannot easily distinguish these two. The proportion of stochastic effects in a complex trait or disease is problematic to estimate. Feinberg and Irizarry (2010) proposed a new non-Lamarckian theory for the role of epigenetics in evolution suggesting that even if a genetic variant does not change the mean phenotype, it might play a role in phenotypic variability mediated by stochastic epigenetic variations.

Twin Studies and Epigenetics

As discussed above, phenotypic variation at the individual/organism and cell level stems from a combination of genetic variation and environmental influence. Compared to other types, twin study designs are a powerful epidemiological tool (Boomsma et al., 2002) that can be used to disentangle and quantify the contributions of the genes; shared and/or individual environments; and the interactions between genetic and environmental factors (Van Dongen et al., 2012; Bell et al., 2012). Indeed, study designs that use unrelated subjects are not able to detect the relative proportions of environmental factors and their interactions with the genome in specific phenotypes, due to the large discrepancies between unrelated subjects at a genomic, age, and environmental level. Utilizing family-based designs or adoptive study designs reduces the impact of genetic variation and theoretically allows us to better define the role of environmental factors. An advantage of twin studies is that several twin registers exist worldwide and the data from these studies are freely available. Twin registers offer a wider diversity of twins thereby facilitating a diversity of studies such as environmental effect, genotype-by-environment-interaction, and the contribution of specific polymorphisms to the total genetic variance in specific complex traits and diseases.

The Classical Twin Study

The classical twin study has been performed since the 1920s and compares phenotypic resemblances between monozygotic and dizygotic twins for one trait or disease. This study design is able to separate genetic and environmental effects (as well as shared and unique environment) and, so, to define heritability of a trait or disease (Boomsma et al., 2002; Rahmioğlu and Ahmadi, 2010). The correlation of a common phenotypic trait between twins (denoted as r_{MZ} for MZ twins or r_{DZ} for DZ twins) depends on their shared genetic and shared environmental variation. This correlation can change with time. If the phenotype under study has a high heritability, then there is a larger concordance in MZ twins compared to DZ twins. Discordance in MZ twins ($d_{MZ} = 1 - r_{MZ}$) for a common phenotypic trait is the noncorrelated phenotypic variability and this depends upon variation at both the genetic and environmental levels. Also the degree of such discordance can change over time.

The estimation of heritability is essential in identifying the major factors influencing complex traits and diseases. More concretely, the term heritability of a phenotypic trait is used to describe the proportion of the total phenotypic variation of this trait that is explained by genetic variation in a given population. The phenotypic variation in a trait (P) can be partitioned into the contributions from latent genetic (G) and environmental (E) factors, and gene–environment interaction (G×E). To a lesser extent, there is a stochastic influence inside each cell (S). This latter is considered as an unique internal environmental factor, such that $V_P = V_G + V_E + V_{G\times E}$. Estimating heritability helps to define the discordance between twins and therefore the role of environment. The latter plays an important role in epigenetic modifications. The exclusion of known and fixed environmental factors such as population, sex, age, cohort, and tissue are usually done in order to study only unobserved genetic and environmental factors and remove some confounders. Theses exclusions assume that these environmental factors do not interact with the genetic variations and other environmental factors. Consequently, the interpretation of heritability should be done cautiously to avoid misconceptions (Visscher et al., 2008).

Three main twin methodologies are used to quantify heritability. Whatever the method used, the computation of heritability is easier and importantly more accurate than those performed on unrelated subjects. A first method is based on MZ twins separated in infancy and reared apart (MZA twins). Assuming that V_E is negligible for MZA twins because of their early separation, interclass correlation between MZA twins (r_{MZA}) becomes an estimate of broad-sense heritability (H^2). In many cases, however, V_E is larger than zero and so, r_{MZA} data tend to yield overestimates of heritability. Despite the power of the MZA design for estimating heritability, the rarity of twins reared apart nowadays generates small samples that are difficult or impossible to replicate.

Two other methods are based on classical twin studies with two further assumptions: first, that MZ twins have identical genomes and DZ twins share 50% of DNA variants and second, that both MZ and DZ twin pairs share the same common environment contributing to total phenotypic variance. Falconer's estimate (Falconer, D. and Mackay, T., 1996) provides a simple first impression of the magnitude of genetic influence in using MZ and DZ intraclass correlation (r). From a mathematical perspective, this comparison allows the assessment of the narrow-sense heritability (h^2) of the trait or disease (or broad-sense heritability if nonadditive genetic variations are incorporated in the formula). This heritability is computed as being twice the difference between monozygotic (r_{MZ}) and the same sex dizygotic (r_{DZ}) concordance rate, that is $h^2 = 2 \times (r_{MZ} - r_{DZ})$, while the shared environment factor is $|r_{MZ} - h^2|$ from MZ twins or $|r_{DZ} - h^2/2|$ from DZ twins. The twin correlation is computed as the addition of additive genetics ($A = h^2$) and common environment (C) factors and the covariance between them, that is, $r_{MZ} = A + C + cov(A,C)$ and $r_{DZ} = ½A + C + cov(½A,C)$, and is close to Pearson's correlation coefficient (variation between −1 and 1).

The second method is the model-fitting analysis of twin data using Restricted Maximum Likelihood (ReML) (Rijsdijk, F.V. and Sham, P.C., 2002), also known as the structural equation modeling (SEM) approach. It allows a more extensive separation and quantification of the observed phenotypic variance into its genetic and environmental components: additive genetic variance (A), nonadditive genetic variance [D (dominant) + I (epistatisis)], shared (or common) environmental variance (C), gene–environment interaction (G × E), and specific (or unique) environmental variance, which also contains measurement error (U (unique) + S (stochastic) + ε (errors in measurement)). The classic model of phenotypic variation is expressed as $V_P = V_A + V_C + V_E$. Two estimators of heritability are commonly defined. First, broad-sense heritability (H^2) takes into account total genetic variation (V_G) when we can define the proportion of all genetic variation (additive and nonadditive); thus $V_P = V_A + V_{D+I} + V_C + V_E$ and $H^2 = V_G/V_P$. Second, narrow-sense heritability (h^2) takes into account only the additive variation of total genetic variation (V_A); thus $V_P = V_A + V_C + V_E$ and $h^2 = V_A/V_P$. However, sometimes ReML can fail to converge when A is very small and also, no negative heritability values are allowed to be computed.

Because of the basic assumptions of the two latter methods, both formulae may lead to underestimates of heritability. Indeed, human DZ twins may share more than 50% of their genetic alleles because of parental homozygosity and assortative mating. Both effects inflate r_{DZ} but not r_{MZ}. Falconer's method can overestimate heritability by underestimating r_{DZ} and overestimating r_{MZ}. Indeed, r_{DZ} is underestimated by the computation of G × E interaction and potentially a sex difference in DZ twins, while r_{MZ} is overestimated by the calculation that identical twins and fraternal twins experience the same degree of environmental similarity. This latter assumption is likely to be violated because of greater similarity in the treatment of MZ twins by other people and the more similar intrauterine environment of MZ twins. On the other hand, Structural Equation Models estimate the proportion of different variables of models based on real data. A comparison between these two methodologies from a simulation of real fMRI data in a twin study showed that both classical ReML estimation and a variant of ReML with Bayesian priors on the variance parameters are more accurate than Falconer's method in both bias and standard deviation comparisons (Ang et al., 2012).

Overall, these studies highlight the power of twin studies to estimate heritability and thereby discordance, even if they may sometimes slightly overestimate heritability and underestimate the contribution of environmental factors.

The Trait/Disease-Discordant Monozygotic Twin Study

The discordant monozygotic twin study, also called the cotwin control method, is a powerful type of case–control study, eliminating genetic effects and subtracting shared environmental factors (Hogenson, 2013). It also has the advantage of completely adjusting for age and cohort effects and minimizing the effects of family and early life influences.

The studies of disease discordance between MZ twins have shown that even for heritable traits there is considerable discordance (Boomsma et al., 2002; Van Dongen et al., 2012) such as 61% of discordance for type I diabetes, 58% for type II diabetes (Condon et al., 2008) and 70–100% of discordance for different cancer types (Lichtenstein et al., 2000). This study design has allowed for the observation of the effect of specific genetic variations such as trisomy 21 (Bonilla et al., 2013; Letourneau et al. (2014)) or Mendelian inherited disorders and chromosomal abnormalities (Zwijnenburg et al., 2010). It also can explore environmental or stochastic factors, such as moderation alcohol consumption, which appears to act beneficially on bone health in female twins without apparent mediation by bone metabolism (Williams et al., 2005), or hemophilia related to a difference in randomization of X-inactivation, of which 30% comes from spontaneous mutation (Bennett et al., 2008).

The discordant MZ model also allows the exploration of causal relationships between two common traits, that is, whether they arise from shared genetic or environmental factors. For example, although autism spectrum disorder (ASD) has a high heritability estimate, Wong et al. (2014) showed that nongenetic factors play a key role in MZ twin discordance. They found that DMRs are site-specific and some are ASD case and family specific. The disease/trait-discordant MZ twin study is the most important and frequently used study to understand the environmental effect on the tuning of phenotype via the proxy that is epigenetic modification (Czyz et al., 2012).

The Multivariate Twin Study

Extension of models to several phenotypes that are potentially influenced by the same and/or different genetic and environmental factors, called multivariate twin models, helps us to unravel causality. Kendler et al. (1987) integrated both phenotype and endophenotypes in his model, to determine their common genetic etiology. Surprisingly, in this study, comorbidity between major depression (MD) and generalized anxiety disorder (GAD) corroborated that the two diseases share genetic factors, but their environmental effects discriminated them. Lervolino et al. (2011) explored the major symptom dimensions of Obsessive-compulsive disorder (OCD). They found that although heritability estimates ranged from 38% to 47%, independent A and E factors specific to each dimension of this disorder explain the remainder of the variance and C was negligible. Thus, the multivariate twin models allow us to explore the causes of comorbidity of two or more traits and test for G×E interactions. It can easily be extended to explore common and unique epigenetic modifications in common traits and diseases.

The Longitudinal Twin Study

Another extension is the longitudinal twin study, which follows the same cohort during a long period. It highlights the changes of a trait over a lifetime, related to environmental and G×E factors. It allows for the monitoring of genetic and epigenetic modifications depending on environmental factors. One example showed that DNA methylation differs in early childhood between young twins and that it was not stable over time (Martino et al. 2013). Using incident disease samples one can pinpoint potentially causal changes (Ng et al., 2012). For example, Heyn et al. (2013b) highlighted the docking protein DOK7 as a candidate for blood-based cancer diagnosis in a cross-section study from a cohort of 15 discordant MZ twins, in which blood samples in a subsample were taken several years before or after cancer diagnosis. This outcome was validated in 21 other discordant MZ twins by pyrosequencing.

Adding other omics data (Bell et al., 2014) or twins' relatives (Weber-Lehmann et al., 2014), the timing of the *de novo* variant or the stability of associations between epigenetic modifications and other omic or phenotypic data, may be defined. For example, Bell et al. (2014) observed both longitudinally stable and variable regions among the 100 top-ranked DMR effects on pain-sensitivity, but the top nine MAP-DMRs were predominantly stable with three-year data and showed altered gene expression in skin tissue.

The Twin Study Combining Different Omic Data

Epigenomic studies may include genotyping or sequencing and other omic data such as RNA-seq, Chip-seq (Van Dongen et al., 2012), RIBO-seq, or metabolomic data (Petersen et al., 2014). In MZ discordant pairs, if the difference between MZ twins cannot be explained at the DNA sequence level (Bruder et al., 2008; Weber-Lehmann et al., 2014), the combination of epigenetic data with other omic data will help to determine nongenetic factors responsible for the change in the trait or disease or to define potential biochemical mechanisms. Grundberg et al. (2013) combined DNA methylation variation (meQTL and meSNP) with gene expression (eQTL) and chromatin mark data (ChiP-seq from ENCODE) in a twin study. They showed a slight enrichment for negative correlation between DNA methylation and gene expression levels in promoter, gene-body regions, and 3′ UTR; but a positive correlation between gene-body methylation and gene expression level. This latter finding might improve transcription efficiency of actively transcribed genes. Additionally, they observed that a significant enrichment of expression meQTLs found in proximal regulatory elements (promoters) compared to all meQTLs for adipose tissue as well as other tissues. The expression meQTLs are also significantly enriched in distal regulatory elements (enhancer) in adipose tissue and metabolic disease loci. This latter outcome confirms that enhancer elements are involved in tissue-specific gene regulation.

Twin Studies Exploring Epigenetic Modifications in Trait or Diseases

Power to Detect Epigenetic Changes in Disease and Complex Trait

Epigenome-wide association studies (EWASs) explore the association between variation in epigenetic sites and a particular phenotype, without an a priori hypothesis. They are similar in concept to genome-wide association studies (GWAS). Statistical power to detect a phenotype-associated epigenetic variant should be a major criterion in EWAS study design. The power of an EWAS is the probability that an EWAS will find a statistically significant association between a trait/disease and epigenetic modifications, given that such an association exists. Power to detect disease-related epigenetic modification is affected by many factors. These include, but are not limited to the choice of epigenetic modifications; study design; "the effect size of [..]" the epigenetic modification "[..] on disease, the concordance of [..]" epigenetic modification "[..] levels between MZ twins at the locus of interest; the sample size; as well as the sensitivity, coverage, and reproducibility of [..]" the epigenetic modification "[..] assay" (Bell and Saffery, 2012). In addition, potential confounding and mediator factors, the choice of tissue and its cell composition, and the stability of the DNA methylation variants over time are also important (Jaffe and Irizarry, 2014).

First, the detection of epigenetic states depends on the accuracy and coverage of the technology selected. For example, methylation arrays such as the Illumina 27k and Illumina 450k arrays do not allow investigation outside of the predesigned probe set and simultaneous interrogation of both genetic mutation and epigenetic modification. A set of recent articles (Chen et al., 2013; Harper et al., 2013; Price et al., 2013) highlights additional technical problems with the probe design and analysis methods used by the Illumina 450k array. Some of them are relevant to other technologies such as polymorphic CpGs and multiple alignments of probes or reads to genome. An important step relevant to analysis of most methylation detection technologies is mapping back the probes or reads to the genome, which is classically done using a reference genome. Consequently, during the study of DNA methylation with Illumina 27k and 450K platform, probes containing

common SNPs or overlapping CNVs anywhere in the sequence are excluded, but the a priori knowledge of each individual's genotype will be required to make an appropriated interpretation and remove only probes affected by SNPs of samples.

Another important step is the definition of epigenetic regions. Some consider single-CpG sites, called differentially methylated positions (DMPs), while others take into account entire continuous genomic regions, which may contain multiple CpG sites. There are currently three types of epigenetic regions considered in epigenetic studies according to variables compared between groups: differentially methylated regions (DMRs) (Jaffe et al., 2012a) having a difference of mean between groups, variably methylated regions (VMRs) (Jaffe et al., 2012b) having a difference of variance between groups, and differentially variably methylated regions (differentially VMRs) (Ahn and Wang, 2013) having a difference of both mean and variance between groups.

Batch effects as well as other confounding factors such as age, population, smoking, and cancer status should be considered early in the study design and in the analysis (Harper et al., 2013; Jaffe and Irizarry, 2014). Other criteria playing a role in the interpretation of epigenetic change are the choice of biological annotation (Price et al., 2013) and network software (Harper et al., 2013), and the management of 'co-methylation' of probes (Liu et al., 2014).

Although MZ twins studies reduce genetic and shared environmental noise (age, early life environment), the composition of cell types and the timing of cell cycle phase across cells in each sample may differ between MZ twins and relate to the phenotype studied. Although cell counts within twin pairs are more similar than between unrelated individuals, as blood composition is highly heritable with a heritability of 61–96% (Evans et al., 1999), there is still a need to perform statistical analysis to control for blood cell composition (Jaffe and Irizarry, 2014). Houseman et al. (2012) designed a method which adjusts for the cell mixture distribution of white blood cells based on the Illumina 27k array, and extended this approach to Illumina 450k array data, with a further extension including reference-free correction. More recently, Zou et al. (2014) also proposed a reference-free method, FaST-LMM-EWASher, to correct for cell type composition. Other methods such as Jaffe and Irizarry (2014) have also been recently developed. These are currently being adapted for application to related samples, such as in twin studies.

The distribution of the studied epigenetic element often has a nonnormal distribution in a sample of individuals. It is possible to transform the values, for example, using a natural log transformation, but the interpretation becomes more difficult. Moreover, variance across the spectrum of methylation is not equal (Relton et al., 2012). Consequently, if the distribution does not conform to normality, the test statistic used should be nonparametric. It is possible to use linear regression but as with all statistical models, there are some assumptions that must be checked, such as constant variation and normality of error/residuals. The robustness of the model should be tested with, for example, resampling methods (permutation, bootstrapping). As the model is applied on a large number of epigenetic sites, multiple testing corrections such as False Discovery Rate (FDR) or Bonferroni adjustment should be applied with stringent threshold. Eventually, replication and validation studies should be performed to validate the outcomes.

Kaminsky et al. (2008) estimated the power to detect differential methylation effects using a high-throughput epigenomics microarray described by Schumacher et al. (2006) in a candidate gene analysis (CpG islands proximal to the homeobox DLX1 gene). They showed that a fold change of 1.2 was sufficiently greater than the null experimental threshold (1.15 null fold change threshold for technical variance) to detect differential methylation with 80% power and type I error of 0.001 after FDR adjustment. To detect a fold change of 1.2 with 80% power, the sample size should be between 15 and 25 of phenotypically discordant twin pairs, depending on number of technical replicates (1 replicate = 25 twins pair versus 4 replicates = 15 twins). The more the number of technical replicates increased, the more power increased, and the more technical variance decreased. Wang (2011) also estimated the power of EWAS but for the case-control design under different parameter settings with a sample size of 250 cases and 250 controls. Other approaches to quantifying methylation effects and power estimations have also been proposed, and using the methOR or methylation odds ratio to describe epigenetic effects (Rakyan et al., 2011b), using generalized regression methods to detect DMRs (Jaffe et al., 2012a) or differential VMR (Jaffe et al., 2012b), and using the first and second moments of methylation distribution (Ahn and Wang, 2013). These methods can also be extended to the epigenetic study of discordant MZ twins.

Epigenome-Wide Association Scans for Complex Traits and Diseases

Epigenome-Wide Association Studies explore variation in epigenetic sites associated with phenotype or environmental factors without an a priori hypothesis (Rakyan et al., 2011b). They are analogous to genome-wide association studies (GWAS), but epigenotype can be considered as an exposure or an outcome or also a mediator. Initially reported EWAS (**Table 3**) to date used the Illumina 27K assay (for example Bell et al., 2012; Gervin et al., 2012), and more recently the Illumina 450K platform (for example, Grundberg et al., 2013; Heyn et al., 2013b; Joubert et al., 2014), as well as high-throughput next-generation sequencing technologies, for example, RRBS (Baranzini et al., 2010) or MeDIP-seq (Bell et al., 2014; Rakyan et al., 2011b; Michels et al., 2013) have reviewed in further detail EWAS design and some examples.

EWAS' may be performed using many study designs e.g., case–control, family or discordant MZ twins. Two important steps in any study are the size of the replication sample and the strategy for validation by other methods. A meta-analysis EWAS combining a discovery discordant MZ twin study and a follow-up unrelated individual study using MeDIP sequencing was used to explore epigenetic effects in pain sensitivity (Bell et al., 2014). This meta-analysis EWAS allowed the definition of nine pain-related phenotype differentially methylated regions (pain-DMRs) without an a priori hypothesis in blood samples. The analysis was performed in two distinct samples, 50 MZ twins identifying about 100 pain DMRs and 50 unrelated individuals identifying 22 pain DMRs respectively. A pain sensitive meta-analysis (MA) highlighted

Table 3 Epigenome-wide epigenetic studies in twins. The list is obtained from a Pubmed search with search terms 'Epigenetic,' 'twin,' 'DNA methylation,' 'histone,' 'microRNA' listing all published studies up to 30 April 2014, without thresholding on sample size

Phenotypes/disease	*Sample Tissue/cell source*[a]	*Epigenetic modification*	*Epigenetic assay*[b]	*Analysis replication*[c]	*Major findings*	*References*
Aging	80 twins; lymphocyte cells; skin cells; muscle and abdominal tissue biopsy	DNA methylation; histone modification	High-performance capillary electrophoresis; AIMS	Anova; replication; validation	Epigenetic drift varies over time and between tissues, but the same overall manner	Fraga et al. (2005)
Risk-taking behavior	1 discordant Female MZ pair; peripheral blood cells	DNA methylation	Microarray array	Paired t-test; replication; validation	Association of risk-taking behavior with 1.2 fold change in DNA methylation of locus DLX1	Kaminsky et al. (2008)
Age and gender, genotype	23 MZ twin-pairs and 23 DZ twin-pairs + 96 healthy controls; whole blood	DNA methylation	Illumina GoldenGate	LMER	Strong association of genetic variant with DMR in cis	Boks et al. (2009)
Heritability of epigenetic change + Twinning process	114 MZ twins + 80 DZ twins; WBC, buccal cells and gut biopsies	DNA methylation	12K microarray array	Methylation difference, ICC; validation in animal studies	Concordance level of methylation: diochorionic MZ > monochorionic MZ > DZ	Kaminsky et al. (2009)
Multiple sclerosis (MS)	3 MZ pairs discordant for MS; $CD4^+$ T cells	DNA methylation; gene expression	Illumina RRBS	N.A.	No association of MS with genetic, epigenetic or transcriptome differences	Baranzini et al. (2010), Baranzini, (2011)
Systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and dermatomyositis (DM)	5 MZ twin pairs discordant for each SLE, RA, and DM; 30 unrelated controls; WBC	DNA methylation; gene expression	Illumina GoldenGate	Student's t-test; validation	49 significant DMRs in SLE discordant MZ twins	Javierre et al. (2010)
Autism spectrum disorders (ASD)	3 discordant Male MZ pairs; lymphoblastoid cell lines	DNA methylation; gene expression	CpG island microarrays	Fisher's exact test; validation	73 significant DMRs with ASD;	Nguyen et al. (2010)
Aging	93 healthy Female: 14 MZ and 17 DZ + 31 singleton; PBMCs	DNA methylation	Illumina 27K	Spearman's rank correlation; replication; validation	213 hyper-Methylated DMRs and 147 hypo-methylated DMRs wit aging	Rakyan et al. (2010)
Autism spectrum disorders (ASD)	3 discordant MZ twins + 1 normal sibling for 2 of the twin pairs + 2 autism concordant pairs and unaffected siblings, and 1 pair of normal MZ twins; LCL derived from peripheral lymphocytes	MicroRNA; gene expresion	Custom-printed miRNA microarrays	Hierarchical cluster analysis and PCA; replication; validation	Association of microRNA with ASD and other co-morbid disorders, including muscle and gastrointestinal diseases, as well as with biological functions implicated in ASD, such as memory and synaptic plasticity.	Sarachana et al. (2010)
Systemic lupus erythematosus (SLE)	1 SLE-discordant MZ in case-control study (26 SLE affected and 26 unaffected controls)	MicroRNA	miRXplore microarray product	miRNA ratio calculation: Hy5/Hy3 ratios validation	Association of SLE with 31 miRNAs differentially expressed	Te et al. (2010)

Aging	34 male MZ pair twin (21-55); saliva	DNA methylation	Illumina 27K	Regression model; validation; replication	Association of 88 DMRs with ageing; 3 genes validated in other cohorts	Bocklandt et al. (2011)
Schizophrenia (SZ) and bipolar disorder (BD)	11 SZ-discordant pairs and 11 BD-discordant pairs; WBC	DNA methylation	Illumina 27K	Paired t-test; validation	Association of ST6GALNAC1 gene with major psychosis.	Dempster et al. (2011)
Childhood-onset type 1 Diabetes (T1D)	15 MZ pairs discordant for T1D; $CD14^{+}$ cells	DNA methylation	Illumina 27K	Wilcoxon signed-rank test; validation; replication	Association of 132 CpG sites with T1D	Rakyan et al. (2011a)
Multiple sclerosis (MS)	8 MS patients, 10 healthy donors, 2 female MZ twins discordant for MS; PBMCs	microRNA	GeneChip miRNA array (Affymetrix).	Anova	Association of microRNA differential expressed with MS	Umeton et al. (2011)
Age and chronological	172 female MZ twins (32-80); whole blood	DNA methylation	Illumina 27K	LMER; replication	Association of age with 16 age-related phenotypes DMRs and 490 chronological age DMRs	Bell et al. (2012)
Schizophrenia (SZ)	38 psychiatric control pairs, 15 SZ discordant twins, 27 SZ concordant twins; whole blood	DNA methylation	Global methylation by nonradioactive elongation-assay and promoter specific methylation	Anova	Association of SZ with DNA methylation differential expressed	Bönsch et al. (2012)
Psoriasis	27 MZ pairs discordant for psoriasis; $CD4^{+}$ and $CD8^{+}$ cells	DNA methylation; gene expression	Illumina 27K; illumina HumanHT-12 v3	Paired t-test; replications	No association of psoriasis with DNA methylation and gene expression	Gervin et al. (2012)
Birth weight, aging	22 MZ and 12 DZ twin pairs; 3 neonatal tissues (CBMC, HUVEC, placenta), blood	DNA methylation	Illumina 27K; EpiTYPING	LMER	Association of 7 genes in DZ CBMCs and 1 in MZ HUVECs with birth weight	Gordon et al. (2012)
Type 2 diabetes + exercise intervention	15 men with (FH+) and 13 men without (FH−) a first-degree FH of T2D + 9 T2D discordant MZ pairs; muscle biopsies	DNA methylation; gene expression; mitochondrial density	MeDIP-Chip The human 2.1 promoter DeLuxe tiling array; affymetrix custom-array NuGO-Hs1a520180-GeneChip; HumanOmniExpress arrays	Two-sample Mann–Whitney; validation	Association of DNA methylation differential expressed with T2D and also with exercise intervention	Nitert et al. (2012)
Type 2 diabetes (T2D)	16 discordant MZ; skeletal muscle and adipose tissue biopsies	DNA methylation	Illumina 27K	Anova; validation	Association of T2D with IL8 and PPARGC1A gene in muscle and with MODY and HNF4A gene in adipose tissue	Ribel-Madsen et al. (2012)
Scleroderma	7 discordant MZ and 1 concordant MZ; PBMC	DNA methylation; X-inactivation	MeDIP; NimbleGen array hybridizatio 4-plex array hybridization kit	Methylation peaks with *p*-score> 1.31	Association of scleroderma with 18 hypermethylated and 25 hypomehtylated sites	Selmi et al. (2012)
Intelligence levels (IQ)	17 MZ pairs; PBMC	DNA methylation; gene expression	Array-based genome-wide DNA methylation and gene expression analyses	Anova; validation	No association of IQ with DNA methylation differentially expressed	Yu et al. (2012)
Down's syndrome (Trisomy 21)	1 MZ twin discordant; fibroblasts	Binding-site of DNA-associated proteins; DNA methylation	ChIP seq for H3K4me3	N.A	Association of trisomie 21 with histone modification;	Bonilla et al. (2013)

Table 3 Epigenome-wide epigenetic studies in twins. The list is obtained from a Pubmed search with search terms 'Epigenetic,' 'twin,' 'DNA methylation,' 'histone,' 'microRNA' listing all published studies up to 30 April 2014, without thresholding on sample size—cont'd

Phenotypes/disease	*Sample Tissue/cell source*[a]	*Epigenetic modification*	*Epigenetic assay*[b]	*Analysis replication*[c]	*Major findings*	*References*
Major depressive disorder (MDD)	12 MZ twin pairs discordant for MDD and 12 MZ twin pairs concordant for no MDD and low neuroticism; WBC	DNA methylation	Illumina 450K	Wilcoxon signed-rank test; LMER; replication	No association of MDD with DNA methylation;	Byrne et al. (2013)
Type 1 diabetes (T1D)	Quadruplets (2 sisters with T1D-1 and T1D-2, 1sister with Pre-T1D and 1 healthy control sister); $CD14^+$ monocytes and $CD4^+$ T cells	DNA methylation	Illumina 450K	Cluster analysis; replications	Association of T1D with 164 DMPs	Disanto et al. (2013)
Systemic lupus erythematosus (SLE)	1 MZ twins discordant; PBMC	DNA methylation; gene expression	Genotype using Illumina human 610-Quad BeadChips; Illumina 27K; Agilent 4X44k	N.A.	Association of SLE with CpG methylation and gene expression levels different for 10 genes	Furukawa et al. (2013)
Metabolic traits	648 twins Used (97 MZ pairs, 162 DZ pairs, and 130 singletons); adipose tissue	DNA methylation; gene expession	Illumina 450K; IlluminaHT12 array; combination of Illumina arrays (HumanHap300, human-Hap610Q, 1M-Duo, and 1.2MDuo 1M).	LMER; replication; validation	Association of metQTL with metabolic-trait or disease loci in enhancer; association meQTL with adipose tissue-specific	Grundberg et al. (2013)
Breast cancer	3 discordant MZ twin pairs; whole blood	DNA methylation	Illumina 450K	Wilcoxon rank sum paired test; validation	*DOK7* as a candidate for blood-based cancer diagnosis given a hypermethylation before tumor diagnosis	Heyn et al. (2013b)
Schizophrenia (SZ)	24 medication-free patients with SCZ and 23 non-psychiatric controls + 3 MZ twin discordant for SCZ; peripheral leukocytes	DNA methylation	Illumina 450K	Paired t-test	Association of SZ with 234 DMPs	Kinoshita et al. (2013)
Twin–twin transfusion syndrome (TTTS)	14 individuals (4 twin pairs who survived TTTS; following corrective surgery 6 sole survivors); Peripheral blood; saliva	DNA methylation	Bisulfite pyrosequencing; illumina 27K	LMER	Association of TTTS with hypomethylation of the LINE1 repetitive element	Marsit et al. (2013)
Aging	10 MZ and 5 DZ twin pairs; buccal	DNA methylation	Illumina 450K	Paired t-test; replication; validation	Association of aging with 1/3 of the CpGs sites assayed	Martino et al. (2013)
Rett syndrome	1 MZ for the severity of discordant (milder and more severe); PBMC and skin fibroblasts	X-inactivation; gene expression; DNA methylation	HUMARA; qRT-PCR; Illumina 450K; ABI Prism 310 sequencer; Whole-genome sequencing using HiSeq2000 sequencers	Value of DiffScore of Illumina software; validation	Association of Rett syndrome with 3 DMRs	Miyake et al. (2013)

Autism spectrum disorder (ASD)	50 MZ twin pairs (discordant and concordant for ASD, ASD-associated traits and no autistic phenotype.); Whole blood	DNA methylation	Illumina 27K; Illumina HumanOmniExpress BeadChip	Replication	No association of ASD or ASD-related trait with differential global in DNA methylation, but site-specific such as NFYC promoter;	Wong et al. (2013)
Heat pain sensitivity	50 MZ twins discordant + 50 unrelated individuals longitudinal data for 33 individuals in 50 discordant MZ twins at sampled 2–3 years apart; whole blood	DNA methylation; gene expression	MeDIP-seq	LMER on 2 independent EWASs + meta-analysis; validation	Association of strongest signal in the pain gene TRPA1	Bell et al. (2014)
Major depressive disorder (MDD)	27 UK discordant MZ twin pairs + 23 Australian MZ twin pairs; whole blood cell	DNA methylation; gene expression	MeDIP-seq	LMER; replication	Association of MDD with hypermethylation within the coding region of ZBTB20 and 17 DMRs of genome-wide significance; No association total gene expression level of ZBTB20 with MDD;	Davies et al. (2014)
Congenital renal agenesis	1 discordant MZ twin pair; whole blood cell	DNA methylation	Illumina RRBS; exome- seq	N.A.	Association of Congenital renal agenesis with 514 DMRs in 25 genes	Jin et al. (2014)
Down's syndrome (Trisomy 21)	1 trisomy 21 discordant MZ (T1DS, T2N) + 16 other cohorts of trisomy 21 and normal unrelated individuals; forearm primary fetal skin fibroblasts (T1DS + T2N); primary fibroblasts from umbilical cord tissue	Gene expression + binding-site of DNA-associated proteins + DNA methylation	RNA-seq in Illumina HiSeq 2000 and on the Illumina Hiseq 2500; H3K4me3 ChIP-seq on a HiSeq2500; DNase I hypersensitivity mapping; Illumina RRBS	Paired-t test technical replication: 4 replication: mouse	Definition of gene expression dysregulation domains (GEDDs); associated T21 with regions associated with nuclear lamina proteins or DNA-synthesis phase of the cell–division cycle;	Letourneau et al. (2014)
Type 1 diabetes (T1D)	3 MZ twin pairs discordant for T1D and 6 T1D-concordant MZ twin pairs; lymphocyte cell lines	DNA methylation	Illumina 27K	Paired LIMMA test FDR correction; validation	Association of T1D with 88 CpG sites	Stefan et al. (2014)

nine MAP-DMRs of which one was in the promoter of TRPA1, an established pain-sensitivity gene. The 100 top-ranked MAP-DMRs had significant positive correlation between levels of methylation in blood and brain from two postmortem donors and a negative correlation with skin gene expression levels, as expected, which suggests that blood may be a relevant surrogate tissue in this example.

Twin Studies, Epigenetics and Environmental Influences on Diseases

Several epidemiological studies have worked on the association between epigenetic modifications and complex traits, as well as the relationship between epigenetic modifications and these environmental factors (Cortessis et al., 2012). **Tables 3** and 4 (Supplementary Data) reports examples of twin studies exploring the relationship between epigenetics and complex traits or diseases and highlights that most of these twin studies are disease-discordant MZ twins. Few examples are described below.

Smoking is considered to be one of the most important risk factors for many diseases, such as heart disease, chronic obstructive pulmonary disease, stroke, acute respiratory diseases, and cancer. Epigenetics allows for the opportunity to study how linking environmental factor, methylation, and gene expression could give insights into the biological mechanisms underlying multiple diseases. One study has revealed that active smoking as well as secondhand tobacco smoking may trigger breast cancer (Luo et al. 2011). Moreover, levels of DNA methylation in breast cancer such as on tumor suppressor genes change, according to both smoking exposure and diet (Luo et al., 2011). On the other hand, a discordant MZ twin study working only on sporadic breast cancer facilitated detection of 403 DMRs including known and novel potential breast cancer genes (Heyn et al., 2013b). Moreover, they showed that the docking protein DOK7 seems to be a potential candidate as a blood-based cancer diagnostic.

Despite increasing associations between epigenetic modifications, environmental factors, and disease, it is still difficult to gauge if epigenetic biomarkers are the causes or the consequences of disease. Causal modeling has been suggested as an approach to answer this question but may not be definitive (Haslberger et al., 2006; Baedke, 2012; Bellavia et al., 2013). Bellavia et al. (2013) showed with elegance the effect of coarse and fine particulate-matter on blood pressure via DNA hypomethylation by using a mediation analysis. Longitudinal studies, if started early enough, will hopefully allow us to distinguish between cause and consequence and to define potential diagnostic biomarkers.

Future Perspectives and Limitations

Limitations

The study of certain complex traits and diseases from twin registers may be difficult given that the number of discordant MZ twin pairs (sample size) is not large enough to detect significantly differentially modified regions, particularly if we study rare diseases. Moreover, following twins for long periods is a recurrent major challenge for twin registers.

Future Prospects

The detailed study of epigenetic markers, other than DNA methylation, using discordant twin studies or in single cell would improve our knowledge of epigenetics immensely. This will depend on advances in technology making high-throughput methods feasible, such as for example, the LC-MS/MS method that was being recently developed to measure global histone modifications (Zhang et al., 2010), for ChIP-seq (Gilfillan et al., 2012), or for single cell (Lorthongpanich et al., 2013; Nawy, 2013).

Combining epigenetics with other omics data will allow us to better understand the relationship between epigenetic factors, omics data, and environmental factors for the trait/disease of interest, such as for example (Petersen et al., 2014), who analyzed the association between metabolites and DNA methylation. Recently, Letourneau et al. (2014) studied the combination of data from DNA methylation, gene expression, and histone modification to unravel the origin of the perturbation of gene expression in Down's syndrome. They discovered that differential gene expression regions are organized into genome-wide domains, not only on chromosome 21. These regions, denoted gene expression dysregulation domains (GEDDs), could be either upregulated or downregulated and were not correlated with differential DNA methylation, but with H3K4me3 profiles. This discovery opens a new door to unravel complex traits and diseases and it will allow us to understand the impact of environmental factors on phenotype via epigenetic modifications. If similar multi-omic data studies are performed at the population level, the stratification of exposure effect or of treatment efficacy may be identified.

Further work in mediation analysis should lead to the better estimation of the effects of environmental exposure on a phenotype mediated by epigenetic postexposure changes (Bellavia et al., 2013). This would require significant relationships between exposure-outcome, exposure-mediator, and mediator-outcome. Such studies will allow us to understand disease mechanisms and the mediator role of epigenetic changes. Furthermore, they will help to identify biomarkers that may predict disease or inform us about prognosis.

There are at least 10 times as many bacteria as human cells in the body (Eckburg et al., 2005). Epigenetics, as well as the microbiome can constitute proxies of environmental exposure to tune gene expression and, at high level, phenotype. The study of the relationship between genome, phenotype, and endophenotypes (epigenetics, microbiome) are crucial to explore their interactions and symbiotic and pathogenic actions on the host. Using twins will hopefully allow us in the future to unravel the relationship between microbiome and epigenome on the development of disease (Steward et al., 2013).

Each phenotype of each individual is a subtle, personal, and dynamic combination between genetic, environmental, and stochastic factors. Thus, individuals via their behaviors, diets, and lifestyles can act directly or indirectly on their epigenetic markers and consequently, on their phenotypes (Crews, 2008; Powledge, 2011). In medical perspective, complex diseases could be treated by personalized medication being able to act on or by epigenetic markers, called epigenetic readers, erasers, or writers, according to their epigenetic mechanisms

(Szyf, 2009; Cohen et al., 2011; Lu et al., 2012). Additionally, twin studies could also help in modern pharmacogenomics studies (Rahmioğlu and Ahmadi, 2010).

Acknowledgments

Twin Studies in Demography

Jere R Behrman, University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Twins studies are used to describe certain characteristics of populations, estimate determinants of population quantity and quality, and identify impacts of critical components of population quantity and quality on each other and on other outcomes. They share in common use of special properties of twins such as shared genes at conception for monozygotic (MZ) twins or very short birth spacing, but use various approaches with different assumptions for different purposes, in order of their frequency of application: (1) ACE model genetic-environmental variance decompositions; (2) MZ twins fixed-effect estimates with controls for endowments; and (3) investigating the quality–quantity fertility model.

Introduction

Demography traditionally has focused on three factors that affect the population quantity: fertility, mortality, and migration. A broader view of human demography also includes population quality – health status, nutritional status, and education – as well as other behavioral outcomes such as marital status, labor force status, and occupational status. Twins studies have been used to attempt to inform the impacts and determinants of population quantity and quality.

Twins studies have been used to describe certain dimensions of populations, to establish the determinants of population quantity and quality, and to identify impacts of critical components of population quantity, and quality on each other and on other outcomes, such as the labor and marriage market returns to health or education. Twins studies share in common the use of special properties of twins, but use a range of approaches with different assumptions for different purposes, around which this article is organized, in order of their frequency of application: (1) ACE model estimates and variance decompositons (additive genetic effects (A), common environment shared by both twins (C) and unique environments that affect each twin differently (E)); (2) monozygotic (MZ) twins fixed-effects estimates of causal effects; and (3) investigating the quality–quantity fertility model.

The second of these approaches exploits identical (monozygotic) twins to control for identical endowments (genetics, environment) at conception. MZ twins are genetically identical at conception, emerging from a single sperm and egg, from which two separate eggs later emerge. MZ twinning occurs at a relatively constant rate among contexts (Kiely and Kiely, 2001). Irrespective of context, MZ twins are rarer than fraternal (dizygotic, DZ) twins. In most prefertility drug populations, about 1 in 85 births are twins (Plomin et al., 2005), of which about a third are MZ, a third same-sex DZ, and a third opposite-sex DZ (Keith et al., 1995).

The other two approaches noted above use both MZ and DZ twins. DZ twins are ordinary siblings in that they are the product of two different eggs and two different sperms. DZs have individual–specific genetics different from family average genetics to the same degree as do other siblings but tend to experience more similar home and broader environments than do other siblings because they are born into the same life-cycle stage of their parents and same larger macroenvironment. The DZ twinning rate is affected by several factors, including maternal age and fertility drugs, and is therefore subject to change over time, across women, and among populations. Some women tend to produce more than one egg at each menstrual period and, therefore, are more likely to have DZ twins, a tendency that may run across generations. Women over 35 years of age are more likely to produce two eggs. Women who have three or more children are also more likely to have DZs. Artificial induction of ovulation and *in vitro* fertilization-embryo replacement can also give rise to DZ and MZ twins. The first twins study approach noted above exploits differences between MZ and DZ twins to identify the basic constructs of interest. The third approach utilizes primarily only the fact of multiple births, not whether they are MZ or DZ.

There are a few datasets of twins raised apart (e.g., Minnesota Study of Twins Raised Apart (MISTRA), Swedish Adoption/Twin Study on Aging (SATSA)). But most twins data include twins that were raised together. Important US twins datasets, for example, include the National Longitudinal Study of Adolescent Health (Add Health) Twin Data, the Midlife Development in the United States (MIDUS) Study, the Minnesota Twins Registry data, the University of Washington Twins Registry data, the Vietnam Veterans Twin Registry Data, and the National Academy of Science–National Research Council (NAS–NRC) Twin Registry of World War II Veterans. There are extensive register-based twins data existing in Australia, Chile, Denmark, Norway, and Sweden, and a few survey-based twins data sets for developing countries (e.g., China). Because twins raised together share both genetic factors – with the genetic overlap at conception being 50% or more (depending on the extent of assortative mating) for DZ and 100% for MZ twins – and important social and economic contexts during childhood and adolescence, they provide an opportunity to better understand how genetic and social endowments affect a variety of behaviors and outcomes that are of key interest to demographers and other social scientists.

Twins are not a random sample of the population. They differ in their developmental environment in the womb and have inferior endowments at birth – lower (Appearance, Pulse, Grimace, Activity, Respiration) APGAR scores; increased incidence of breathing difficulties; and lower birth weight, which has been shown to significantly affect not only infant survival but also adult outcomes (Behrman and Rosenzweig, 2004; Almond et al., 2005; Black et al., 2005). Rosenzweig and Zhang

(2009) summarize the distributions of birth weights from the US white population for twins and nontwins, based on the Minnesota Twins Registry and the US National Longitudinal Survey 1979, and the birth weight distributions for twins and nontwins born in China based on their survey data. In both countries, the average birth weight of singletons is almost 30% higher than that of twins, approximately a 0.7 kg difference. However with respect to a number of observed characteristics, twins differ very little from singletons. Studies on the personality and intelligence of twins, for example, suggest that they have traits very similar to those of nontwins (e.g., Deary et al., 2006). The second twins method above controls for any unobserved characteristics shared by twins, including being raised with siblings born at the same time. So for this approach arguably the aspects in which twins are different from singletons are controlled.

Recent developments have made possible the incorporation of genetic markers in sociodemographic data sets, which clearly enhance the possibilities of incorporating genetics into demographic analyses. The special issue of the *American Journal of Public Health* edited by Kaplan et al. (2013) includes a number of papers that discuss the implications and the limitations of these developments for demography and the social sciences more broadly. These developments may permit identification of the roles of particular genetic markers in various outcomes and otherwise enhance some dimensions of analyses using twins, probably with particular emphasis on the implications of epigenetics for gene–environment interactions in the first, and perhaps the second twins method. But these developments do not eliminate the value of twins studies because, for example, they permit easy characterization of specific genetic markers but not the entire set of genes shared by MZ twins as used in the first twins method, or the control for average family genetics and other shared dimensions of childhood family and neighborhood background experienced at the same life-cycle stage as in the second method or the use of twining as an increase in child quantity that is the essence of the third method.

ACE Model Estimates and Variance Decomposition

The first approach, to estimate heritability and related variance decompositions with ACE or closely related behavioral genetics models, is the most common use of twins in demography and the other social sciences. To illustrate, the Wikipedia article on 'Twin Study' (http://en.wikipedia.org/wiki/Twin_study; accessed 20.09.13.) only includes this approach among the three that are covered in this article.

These analyses generally have been concerned with decomposing the variance of an observed outcome Y ('phenotype') such as fertility or health into the contributions of additive genetic effects (A), common environment shared by both twins (C), and unique environments that affect each twin differently (E) – hence the acronym 'ACE'. The simplest univariate behavioral genetics approach assumes additive genetic models with no assortative mating and with equal environmental influences across MZs and DZs:

$$Y_{ij} = aA_{ij} + cC_{ij} + eE_{ij} \quad [1]$$

where subscripts refer to the *ith* child in the *jth* family in general and to the *ith* twin in the *jth* twinship in twins studies. a measures the extent to which Y_{ij} is affected by genetic endowments A_{ij}, c measures the extent to which Y_{ij} is affected by common environments C_{ij}, and e measures the extent to which Y_{ij} is affected by unique environments E_{ij}. MZ twins are assumed to share 100% of their genes (A) and common environment (C) so that any differences between members of a MZ twinship in this model are due to unique environments (E). The correlation between outcomes for MZ twins (r_{MZ}) is an estimate of $A + C$. DZ twins, like ordinary siblings, are assumed also to share the same C and on average 50% of their genes if there is no assortative mating. In that case the correlation between outcomes for DZ twins (r_{DZ}) is $0.5A + C$. Therefore the additive genetic effect A is twice the difference between the MZ and DZ correlations $A = 2(r_{MZ} - r_{DZ})$ and heritability (h^2) in the simplest univariate ACE model is defined to be the variance in aA relative to the variance in Y:

$$h^2 = a^2\frac{\mathrm{Var}(A)}{\mathrm{Var}(Y)} \quad [2]$$

More recent multivariate behavioral genetics analyses investigate the contributions of genes and the environment to the correlations among multiple outcomes (Plomin et al., 2005). For example, the simplest bivariate ACE model is an extension to two outcomes, say schooling (S) and fertility (F), and allows for cross effects so that, for instance, the determinants of schooling (A^S, C^S, E^S) also affect fertility in addition to the factors that only affect fertility (A^F, C^F, E^F):

$$S_{ij} = a_{SS}A^S_{ij} + c_{SS}C^S_{ij} + e_{SS}E^S_{ij} \quad [3]$$

$$F_{ij} = a_{SF}A^S_{ij} + c_{SF}C^S_{ij} + e_{SF}E^S_{ij} + a_{FF}A^F_{ij} + c_{FF}C^F_{ij} + e_{FF}E^F_{ij} \quad [4]$$

The first three terms in eqn [4] indicate contributions of the three determinants of S (A^S, C^S, E^S) to F and the last three terms indicate contributions of the three factors (A^F, C^F, E^F) that only affect F but not S. Estimation of this bivariate ACE model permits estimation of heritabilities of S and F and the extent to which ACE factors determining S in relation in eqn [3] also determine F in relation in eqn [4]. Estimation of this model, however, does not identify whether the ACE factors determining S determine F indirectly through S or directly. Nevertheless some limited inferences about the possible impact of S on F might be made. In the extreme case in which $a_{SF} = c_{SF} = e_{SF} = 0$, there could not be any impact of S on F. On the other hand, if all the impacts of (A^S, C^S, E^S) on F are through S, $a_{SF}a_{ss} = c_{SF}c_{ss} = e_{SF}e_{ss}$, which can be tested and whether or not satisfied used to establish the maximum possible impact of S on F.

There are many estimates of heritabilities of demographic outcomes, particularly pertaining to the health component of quality. For example related to fertility, Kohler and Rodgers (2003) analyze data on Danish twins born between 1953 and 1970 and conclude that a bivariate behavioral genetics analysis confirms that fertility in this low-fertility setting is subject to important genetic influences and (perhaps somewhat unexpected) genetic variance in fertility is not necessarily shared with genetic variance in completed schooling attainment. Instead, their results show that most genetic variance in fertility is

residual variance that affects fertility but not schooling attainment. Overlapping influences mainly exist for shared environmental factors analyses of females, for whom all shared environmental factors affecting fertility also affect schooling.

A number of questions have been raised or limitations noted about the simple ACE models and, in some cases, extensions developed or empirical evidence presented to attempt to speak to these questions or limitations. Some examples include:

- The assumption of equal common environments for MZ and DZ twins has been questioned and if environments are not common (e.g., $C^{DZ} < C^{MZ}$), then $A = 2(r_{MZ} - r_{DZ})$ above becomes $A + 2(C^{MZ} - C^{DZ}) = 2(r_{MZ} - r_{DZ})$ so if MZ's share more common environments than DZs, in the standard calculation the differences in shared environments are attributed to genetic differences.
- The assumption of no assortative mating seems violated by many studies of assortative mating particularly on schooling and assuming no assortative mating when there is positive assortative mating overstates the genetic contribution (i.e., $A = (s^{-1})(r_{MZ} - r_{DZ})$ where s is the proportion of shared genes among DZs so if s is assumed to be 0.5 when s actually is greater than 0.5 due to assortative mating, A is overestimated); if DZ twins share more than 50% of their genes owing to assortative mating, however, the correlation between the A components across DZs can be increased accordingly by using the actual value of s.
- Epigenetics implies that the expression of genes may differ even for MZ twins; this implies that typical estimates of heritability are lower-bound estimates for heritability at conception because in the simplest ACE model the unique environment E proxies for the part of A altered by epigenetics.
- There may be nonadditive genetics effects (often denoted D for dominance); these can be examined in an ADE model.
- The standard ACE twin design does not permit considering both C and nonadditive genetic effects simultaneously; this limitation can be addressed by expanding the design to include additional siblings.
- Gene–environment correlations are not detectable as distinct effects; incorporating adoption models, or children-of-twins designs may assess family influences uncorrelated with shared genetic effects.
- The implications of standard models of investments in children that endowments of all children in families affect investments in any particular child are ignored (see the second twins study approach below).

As noted, some of these limitations can be dealt with by extending the ACE model or bringing additional information to the analysis. However even if these limitations are dealt with, a fundamental question is why is heritability, a major concern of the ACE literature, of much interest. To illustrate this point, consider **Figure 1** (also see Behrman et al., 1980; Feldman and Lewontin, 1975; Layzer, 1974). In this figure, reaction functions for some outcome (phenotype, such as fertility F) are plotted against the environment (N, combining both C and E). Suppose that genes come only in two forms (1, 2) and reactions of F to changes in N differ for the two gene types as in the figure. Let the dashed line be the average reaction function for the population. The variance of F and the proportion of this variance due to genetics are greater for given environmental changes, the greater the vertical distance between the reaction functions for genetic types 1 and 2 over the range of the change in N. The relative contribution of a small change around N_0, for example, is much smaller than the contribution of an equal change around N_1. Therefore heritability estimates are much different around N_0 than around N_1 even though the reaction functions have the same slopes (and thus indicate the same impacts of changing N on F) around N_0 as around N_1. Within this framework, therefore, estimates of heritability are not a good guide to what happens to F if N is changed. To explore what happens to F if N is changed, the reaction function slopes are needed, not the variance decomposition for F. Obtaining such estimates for changes in such factors as schooling attainment is the focus of the second twins method, discussed next. Also see Kohler et al. (2011) for a recent effort to integrate such concerns with the bivariate ACE framework.

Figure 1 Fertility reaction functions for two genetic types, 1 and 2, and average reaction function all versus the environment.

MZ Fixed-Effects Estimates of Impacts of Demographic Variables or of Other Variables on Demographic Outcomes

The second approach, using MZ twins to control for genetic and other background unobserved confounding factors, is the second most common use of twins for population studies. Social scientists long have used sibling comparisons for this purpose, reasoning that if brothers/sisters are similar with respect to family background and other characteristics, using differences between them in, for example, schooling controls many relevant confounding factors (Griliches and Mason, 1972 is an early study). MZ and DZ twins are more attractive than other siblings in at least one important respect because, as noted above, they share birth dates and, therefore, differences between them are not confounded by family life-cycle differences. Moreover, within-MZ twins estimates also control for genes at conception (for early studies, see Behrman and Taubman, 1976; Behrman et al., 1980).

Twins fixed-effect studies estimate causal effects of one (or more) variable (e.g., own schooling, birth weight, parental schooling, fertility), which may be partly determined directly by unobserved endowments, on other variables (e.g., fertility, mortality, schooling, marital status, spouse characteristics, health-related behaviors and outcomes, social interactions, wages) that are themselves partly determined directly by endowments. Consider the following linear representation of a reduced-form equation relating adult mortality M_{ij} for the *ith* member of paternal family j to his or her schooling S_{ij} and to three sets of unobserved variables that for simplicity are presented as scalars (but which may be vectors) representing (1) endowments f_j that are common among all children of the paternal family j (e.g., exogenous features of paternal family environments in childhood, including family income, parents' human capital, average genetic endowments among siblings, local schooling, and health-related options), (2) the component of endowments that is specific to child i in family j, represented by a_{ij} (e.g., individual-specific deviations from average family genetic endowments), and (3) a random mortality shock that is specific to i in j, inclusive of measurement errors in mortality, represented by v_{ij}:

$$M_{ij} = \beta_S S_{ij} + f_j + a_{ij} + v_{ij} \qquad [5]$$

where β_S is the effect of schooling and the three unobserved variables (f_j, a_{ij}, v_{ij}) are defined in units so that their coefficients are all one. S_{ij} is itself a function of variables that pertain to the paternal family and to the individual children in the paternal family:

$$S_{ij} = \alpha_f f_j + \alpha_a a_{ij} + \alpha_S a_{kj} + u_{ij} \qquad [6]$$

where α_f is the effect of the family-specific endowment f_j on schooling investment in child i, α_a is the effect of the individual-specific endowment a_{ij} of child i on schooling investment in that child, α_s is the effect of the individual-specific endowment a_{kj} of sib k (which is a vector if there are multiple siblings) on schooling investment in child i, and u_{ij} is a disturbance that affects S_{ij} but not M_{ij} except indirectly through S_{ij} (this is a critical assumption discussed below). The stochastic term, for example, might reflect chance events of one twin encountering more inspiring role models that affect schooling attainment but not mortality except through schooling attainment than the other twin.

Note that these relations are related to, but not identical to, the expressions above for the ACE model in the first approach. First, relation in eqn [5] differs from the ACE relations because another outcome S is included among the right-side variables, which indicates a direct effect of one outcome on another that is of central interest in the MZ twins fixed-effects approach. Second, both relations in eqns [5] and [6] differ from the ACE relations in that (1) the family endowments f_j include both the average family (or twinship) component of A and C because there is no need to distinguish between them in this approach and (2) the individual-specific endowment a_{ij}, the individual-specific component of A, is distinguished from the average family component of A. Third, the relation in eqn [6] differs from the ACE relations because the individual-specific component of the other twin a_{kj} (or, more generally, of all other siblings) is included because within family models of investment in children the endowments of all siblings in the family affect the investments in any particular child and parents may allocate resources to their children so as to reinforce or compensate for endowment differentials (Becker and Tomes, 1976; Behrman, et al., 1982, 1995). (Also see discussion of some results below in this section.) Note that relations in eqns [5] and [6] are specified such that the other twin's endowment a_{kj} affects directly S_{ij} but not M_{ij} except indirectly through S_{ij}, a simplifying assumption that can be dropped with no loss in generality.

As is well known, the parameter of central interest β_S is not identified in eqn [5] if α_a or α_f is not zero. β_S is estimated with bias if eqn [5] is estimated across individuals with different values of f_j and a_{ij}. The regression coefficient for an ordinary least squares (OLS) estimate of relation in eqn [5] is $cov(M_{ij}, S_{ij})/\sigma^2(S_{ij}) = [\beta_S(\sigma^2(S_{ij}) + cov(S_{ij}, f_j) + cov(S_{ij}, a_{ij}))]/\sigma^2(S_{ij})$, which is a biased estimate of β_S unless $cov(S_{ij}, f_j) + cov(S_{ij}, a_{ij}) = 0$. Thus, generally, cross-sectional estimates of associations between S and M are biased estimates of the causal impacts of S on M because S is partially proxying for genetic, family background, childhood neighborhood and other endowments.

With no further assumptions, it is clear that β_S, is not identified even if sibling data, including DZ twins, are used to control in the estimation of β_S for common components of endowments f_j because of the specific components of endowments a_{ij}. As long as families or individuals respond to individual-specific differences in endowments, and such differences are important, then sibling estimators do not provide unbiased estimates. Therefore researchers have used MZ twins, between whom there are as minimal as possible endowment differences at conception, to identify β_S in estimates of models such as relations in eqns [5] and [6], which can be rewritten for MZ twins as:

$$M_{ij}^M = \beta_S S_{ij}^M + f_j^M + v_{ij}^M \qquad [7]$$

$$S_{ij}^M = \alpha_f f_j^M + u_{ij}^M \qquad [8]$$

where superscripts M refer to MZ twins. Relations parallel to eqns [7] and [8] can be written for the *kth* MZ twin in the *jth* family. Fixed-effects MZ twin estimators control for all right-side variables in these relations that are common to both members of MZ twinships (including all characteristics of nontwin siblings and whatever is distinctive about being MZ twins). What is and is not controlled in such relations can be seen in equivalent within-MZ twin relations in which all the factors common to the twins are eliminated. Within-MZ-twin estimators are obtained by subtracting relations in eqns [7] and [8] for the *kth* MZ twin in the *jth* family from relations in eqns [7] and [8] for the *ith* MZ twin in the same family. With a within-MZ-twin estimator (or MZ fixed effects), all of the unobserved endowment components in eqns [7] and [8] are controlled so that consistent estimates of β_S are obtained under the maintained assumption that $cov(u, v)$ is zero:

$$M_{ij}^M - M_{kj}^M = \beta_S\left(S_{ij}^M - S_{kj}^M\right) + v_{ij}^M - v_{ij}^M \qquad [9]$$

Thus, MZ fixed-effects estimators identify true reduced-form impacts of S on M under assumptions noted above. Comparisons can be made with estimates of relation in eqn [5] for the same M outcome to learn to what extent estimates of β_S, the impact of S on M, are biased in cross-sectional estimates that fail to control for unobserved endowments f_j and a_{ij}. Comparisons also can be made between MZ

fixed-effects estimates for females and males, among racial and ethnic groups, across birth cohorts, across levels of socioeconomic status (SES), and across countries. Comparisons can also be made between MZ fixed-effects and DZ or other sibling fixed-effects estimators to see if unobserved individual-specific endowments a_{ij} are important so that within-sibling estimates that control only for common family endowments f_j are misleading. Finally, comparisons can be made between DZ fixed-effects and ordinary sibling fixed-effects estimators controlling for birth spacing to investigate the impact of changes in the timing of births and birth order in the estimated impacts.

A major strength of MZ twins fixed-effects estimates, in comparison with ACE estimates (also see Kohler et al., 2011 for an effort to integrate the two approaches), is that under their maintained assumptions they permit estimation of the causal impact of one behavioral variable such as schooling attainment (an indicator of population quality) on other behavioral variables related to population quantity or quality, such as health, mortality, health-related behaviors, fertility, migration, and investment in children. Such estimates often are of considerable interest in terms of prediction or policy assessments. Moreover MZ twins fixed-effects estimates do not require assumptions about MZ and DZ twins having equally shared environments C or the absence of genetic–environmental interactions. It should be noted that instrumental variables (IV) or two-stage least squares (2SLS) are alternative approaches for eliminating bias in estimated impacts of schooling or other variables, but the indentifying instruments used to date for such estimates such as changes in minimum schooling requirements or ages for leaving schooling have the limitation of being local average treatment estimates (LATE) relevant only for those affected by such changes and not for those over the whole distribution of schooling. Differences in schooling for MZ twins, in contrast, tend to occur for many different schooling levels, not just at the minimum required schooling levels or ages, and thus tend to be more like average treatment effects (ATE) estimators (Amin and Behrman, 2014; Behrman et al., 2011; Lundborg, 2013).

MZ twins fixed-effects estimates have been utilized to investigate the impact of schooling on many demographic outcomes – fertility, mortality, own health/disease conditions, own hospitalization, children's schooling and health and nutritional status, spouse's schooling and health conditions – as well as returns to human capital investments in schooling and health in labor and marriage markets (examples include Amin and Behrman, 2014; Amin et al., 2013; Ashenfelter and Krueger, 1994; Ashenfelter and Rouse, 1998; Behrman et al., 1980, 1994; Behrman and Rosenzweig, 1999, 2002, 2004; Behrman and Taubman, 1976; Conley et al., 2006; Li et al., 2008; Lundborg, 2013; Rosenzweig and Zhang, 2009). A common, but not universal, result is that MZ twins fixed-effects estimated impacts of schooling are considerably smaller and often insignificant than OLS estimates, consistent with relations in eqns [5] and [6] and with upward biases in OLS estimates because in OLS estimates S proxies in part for unobserved endowments in relation in eqn [5]. An interesting example is that the coefficient estimate for maternal schooling attainment in relations with the dependent variable being child schooling is significantly positive in OLS estimates but significantly negative in MZ fixed-effects estimates using the Minnesota Twins Registry data for twins born between 1936 and 1955, consistent with the possibility that increasing S and holding endowments constant increases mothers' labor force participation and reduces their time with their children, which in turn reduces the children's schooling attainment (Behrman and Rosenzweig, 2002).

Though the majority of this literature focuses on estimating schooling impacts on various demographic outcomes, there are some studies that use MZ fixed-effects estimates to investigate other types of relations. One example is the impacts of birth weight over the life cycle, in which case MZ fixed-effects estimates of causal effects are larger for schooling and earnings but smaller for adult height and BMI and birth weight for the next generation than OLS estimates, consistent with there being multiple dimensions of unobserved endowments that are controlled in the MZ estimates and negative correlations between underlying intellectual endowments and physical endowments (Behrman and Rosenzweig, 2004). A second example is the estimate of the impacts of fertility and partnership on happiness, in which case controlling for unobserved endowments substantially affects a number of the estimated effects, suggesting that standard analyses of contributions of partnerships and children to well-being are subject to biases, often substantial, both upward and downward (Kohler et al., 2005).

MZ twins fixed-effects approaches also have been used together with relations in eqns [5] and [6] above for DZ twins to explore whether families reinforce or compensate for child endowment differences. Behrman et al. (1994) show how comparisons between the within-twin correlations of human capital outcomes across MZ and DZ twins can be used to identify the individual-specific endowments and the responsiveness of schooling to individual-specific endowments in the family and in the marriage market. The basic idea is to obtain the 'correct' estimates of the impact of schooling on earnings outcomes using relation in eqn [8] with earnings as the outcome and then, conditional on that estimate of β_S, use relations in eqns [5] and [6] for DZ twins to estimate individual-specific endowments a_{ij} and a_{kj} and how schooling investments respond to those endowments. Estimates from two US twins samples indicate that 27 (42)% of the variance in log earnings (obesity) is due to variability in individual-specific endowments (which suggests that they should not be ignored as in DZ or sibling fixed-effects analyses), allocations of schooling reinforce rather than compensate for specific endowments so the family acts to increase inequality among its children (also reported in an earlier twins study by Behrman et al., 1982), and individual-specific earnings endowments of men and their wives' schooling are negatively associated.

Major criticisms of the MZ twins fixed-effects approach and brief reactions to these criticisms include the following four points (see Kohler et al., 2011, for more extensive and more formal discussions of the last three of these):

1. Twins are not representative of the larger population: As noted in the introduction, the MZ twins fixed-effects approach, by controlling for unobserved fixed effects common to the twins, arguably controls for respects in which such twins differ from the overall population.

2. The stochastic terms in relations in eqns [5] and [6] are likely to be correlated: If between-twin differences in S reflect unobserved factors that also directly determine M (or whatever the dependent variable is in relation in eqn [5]) so that $cov(u_{ij}, v_{ij}) \neq 0$, the estimated schooling-mortality impact is still biased in the MZ twins fixed-effect estimator (perhaps the most visible critique along these lines is Bound and Solon, 1999). The sign of this bias is determined by the sign of the correlation. For example, if more favorable *in utero* environments due to proximity to the placenta increase both schooling and health beyond any effect through schooling as suggested by the results in Behrman and Rosenzweig (2004), then the estimate of β_S from eqn [6] is an overestimate of the true value of β_S. The same holds if an accident or illness limits schooling and has persistent negative effects on later outcomes such as increasing age-specific mortality rates. If $cov(u_{ij}, v_{ij}) > 0$ as often seems to be assumed when the independence between the stochastic terms in eqns [5] and [6] is questioned, thus, the MZ twins fixed-effect estimator, all else equal, gives an upper-bound estimate of β_S in which case that the MZ twins fixed-effect estimates of schooling impacts tend often to be smaller in absolute magnitude than the OLS estimates as noted above would seem to be more compeling evidence that the OLS estimates are biased upward in absolute magnitudes. On the other hand, If $cov(u_{ij}, v_{ij}) < 0$ (e.g., the persistent effect of an illness during school ages also, beyond any effects through S, increases life expectancy through directly reducing participating in risky activities), then the MZ twins fixed-effect estimator, all else equal, gives lower-bound estimates of β_S. One possible empirical approach is to include additional variables that might have persistent effects on both schooling and the outcome of interest, such as measures of cognitive ability (Behrman et al., 1980) or birth weight. In these two cases, the estimates of interest are not changed much by including these additional controls, but other applications could reveal different results.
3. Twins react to each other: If there is imitation with respect to the right-side determinant, such as S in relation in eqn [5], there is no bias in either direction for the MZ fixed-effects twin estimator. But if there is imitation with regard to the dependent variable, such as M in relation in eqn [5], the estimated β_S is a lower bound if there is positive imitation and upper bound if there is negative imitation. Of course for some population outcomes such as fertility imitation of outcomes would seem more likely than for others such as mortality. If there is positive imitation on the outcome, the maximum downward bias is 50%, but the actual bias is likely to be considerably less because the maximum is for the unlikely situation in which the other twin's outcome (e.g., fertility) is weighted as much as the own direct determinants of one's own outcome.
4. Measurement error: Fixed-effects estimates in general, including for MZ twins, filter out much of the true signal of S (or whatever the right-side variable is in relation in eqn [5]) without also reducing measurement error, so there is a tendency for more measurement error bias toward zero than in simple cross-sectional estimates. Twin studies that have reports from other respondents (i.e., the other member of a twin pair, the twins' adult children), so that they can estimate measurement error models, report estimated noise-to-signal ratios of 0.04–0.12 (Ashenfelter and Krueger, 1994; Behrman et al., 1994; Ashenfelter and Rouse, 1998; Amin et al., 2013). Therefore a noise-to-signal ratio of about 0.08 is suggestive for the noise-to-signal estimates from these studies, which implies attenuation biases of about 8% for individual estimates and 26% for within-MZ estimates, a fairly substantial effect in the latter. Behrman et al. (1980) observed that estimates of noise-to-signal ratios from other studies could account for up to half of the difference between their fixed-effects estimates and OLS estimates. Ashenfelter and Krueger (1994) and Behrman et al. (1994) introduced use of another report on the twin's schooling to instrument schooling and therefore eliminate the measurement error bias under the assumption that the measurement error in the other report is independent of the measurement error of one's own report. Both studies find that this method for controlling for measurement error increases the estimated returns to schooling in comparison with estimates that do not correct for measurement error. Many, but not all, subsequent studies (including many of those summarized above) use reports from other respondents to control for measurement error.

Quantitiy–Quality Fertility Model

The third approach – but probably less common than the first two approaches – to using twins for population analysis is to use unanticipated multiple births (usually twins) as exogenous increases in child quantity to explore the quantity–quality (Q–Q) fertility model (Becker and Lewis, 1973; Willis, 1973). Rosenzweig and Wolpin (1980a,b) first proposed and implemented this approach, which basically is to estimate effects of an extra birth at parity P due to twins on child quality at previous parities for all women who had at least P births. The incidence of twins at P is used as an instrument to predict the total number of children born in a IV or 2SLS estimation. Early studies found evidence that sibhip size and children's schooling are negatively related (Rosenzweig and Wolpin, 1980b; Hanushek, 1992). But some recent studies (Caceres, 2004; Black et al., 2005; Angrist et al., 2010; Qian, 2009; Li et al., 2008) using twin births to assess the impact of an exogenous increase in child quantity on child quality of nontwins in the same families have found little or no evidence of a Q–Q trade-off with the exception of rural (but not urban) areas of China in the last of these.

Rosenzweig and Zhang (2009) note that these studies do not really examine impacts of total sibship size on children of parity N (or higher) because impacts on the quality of the twins themselves are ignored, perhaps because twins are not comparable to multiple singleton births for two reasons noted in the introduction: (1) twins are more closely spaced and (2) twins have inferior birth endowments. They argue that a key issue for assessing whether existing evidence from twin studies rejects Q–Q trade-offs is thus whether these two features affect investments in nontwins within families. If closer spacing of twins affects relative costs of investing in them vs singleton children and endowments of twins are lower than those of singleton births, then twinning not only may lower average resources per child

due to increases in sibship size, but also may lead to reallocation of resources differentially across children of different birth orders and thus affect inferences about Q–Q trade-offs based on estimates of the effects of twinning on nontwins siblings.

Rosenzweig and Zhang (2009) show that estimates of higher-parity twinning on older nontwin siblings may underestimate Q–Q trade-offs and thus the weak findings in the recent literature may be consistent with the Q–Q model. Given reinforcing behavior, estimates of the effects of twinning on twins and their older nontwin siblings bound the Q–Q trade-offs as long as any economies of scale from twinning are not too large, with estimated effects of twinning on older nontwins providing lower bounds. They also explore additional considerations not incorporated in simple Q–Q models such as public goods and birth spacing. They use the modified Q–Q model with survey data on families with twins and with singletons in China, where the 'one-child' policy that was strictly enforced in urban areas meant that twinning on the first birth resulted in one exogenous extra birth (and likewise for parity two in rural areas where two children were permitted). They find that twin quality is lower than for singleton siblings at N, and that declines in quality for parity-P births are significant so that the basic prediction of the Q–Q model that child quantity increases reduce average quality is not rejected.

Tyranny

Stephen D Reicher, School of Psychology and Neuroscience, University of St Andrews, St Andrews, UK

Abstract

This article reviews the traditional social psychology of tyranny. We show how this is rooted in the assumption that group psychology per se, and more specifically, immersion in cohesive groups, is at the root of both submission to authority within groups (as exemplified by Janis's work on groupthink) and domination over members of other groups (as exemplified in Zimbardo's analysis of his Stanford Prison Experiment). We also show that the evidence does not support this assumption. Cohesive groups do not exclude intragroup criticism and dissent. Moreover, group cohesion is necessary as much to challenge as to impose intergroup domination. We then provide evidence from the BBC Prison Study to provide an alternative analysis of the relationship between group process and tyranny. On the one hand, shared social identity and group coordination empower group members to express group norms and to contest the imposition of out-group norms upon them. On the other hand, the failure of groups leads people to accept the imposition of tyrannical leadership and extreme forms of action. Rather than urging people to avoid groups and the exercise of group power, we conclude that people need to embrace groups and exercise group power in defense of democratic and humane values.

Introduction

Tyranny is the absent presence that haunts and frames social psychology – and indeed the whole of social science – and has done since the end of the World War II (see Waller, 2010). On the one hand, if you search for the term 'tyranny' in the index of a social psychology textbook, it is almost certain you will not find it (of the 24 such textbooks on our shelves, it appears in none). On the other hand, the topics which we study are shaped by our experience of the Nazi dictatorship and, above all, by the Nazi Holocaust. In the words of Gershon Sholem, we are still reacting to "the great historical and social question … how could this happen" (cited in the frontispiece to Baumann, 1981). This is clear in the areas that dominate social psychology – notably work on prejudice, stereotyping, discrimination, and intergroup conflict. It is equally clear in the topics that we have neglected. Before the War, for instance, leadership was widely studied based on the hope that strong and charismatic leadership would provide a solution to the social problems of an industrial age. But after the war, the experience of such leadership led to a wholesale retreat from research into the topic and strong leaders came to be seen more as psychopaths than saviors (Haslam et al., 2010).

Nonetheless, even if social psychology does not address the issue of tyranny explicitly by name, there is certainly a literature which bears on phenomena that could be included under the rubric of tyranny: the ability of people to question authority or express dissent, their willingness to suppress and oppress those who do dissent or who are simply 'other,' and their willingness to condone oppressive authorities. The most obvious examples of this lie in the huge and ever-growing literature on authoritarianism (Adorno et al., 1950) and the more recent literature on social dominance (Sidanius and Pratto, 1999). These explain support for hierarchical and punitive authorities in terms of stable differences between individuals and, as such, one of the most telling criticisms of them derives from observing the realities of their historical point of origin in Nazi Germany. That is, on the one hand, support for tyranny was a collective phenomenon and on the other, it changed dramatically after the War as the collective context changed (Billig, 1976).

Accordingly, our focus in this article will be on the group psychology of tyranny. We will consider first work which bears on intragroup processes – that is, the ability of people to challenge authority within a group. We will then look at intergroup processes – that is, the willingness of people to oppress (or else support the oppression of) members of other groups.

Despite major differences between these two areas, we will see that they share in common the view that the problems lie in the very nature of group psychology and that therefore the answer to tyranny is for people to shun groups and act as individuals. We shall argue that this neglects the fact that it is only as group members that people can challenge inequality and oppression (Haslam and Reicher, 2012a; Reicher, 2004; Tajfel and Turner, 1979) and therefore such an argument ultimately serves to buttress rather than to challenge tyranny. We shall argue instead that the response should be less to do with whether we embrace groups or not than to question the nature and norms of the groups with which we identify.

Tyranny and Intragroup Processes: Janis's Groupthink Research

For nearly half a century, small-group research has been dominated by the concept of 'groupthink' (see Haslam et al., 2006). What is more, the idea has migrated from academia into the public domain and is used to explain everything from the financial crash to the latest fashions. As Fuller and Aldag observed a while back, "Groupthink is presented as accepted wisdom in sources ranging from *Educational Gerontology* to the *Utne Reader*, from *The New Criterion* to *Vogue*" (1998: p. 166).

In his original text, Janis (1972) compared four of the most calamitous decisions in recent U.S. history – neglecting the defense of Pearl Harbor in 1941, invading North Korea in 1950, invading of the Bay of Pigs in 1960, escalating the war in Vietnam between 1964 and 1967 – and contrasted them to two rather more successful decisions – developing the Marshall plan after World War I and the handling of the Cuban missile crisis in 1962. He argued that the former (unlike the latter) were characterized by an overestimation of in-group wisdom, a denigration of the out-group, and (most strikingly) overwhelming pressures toward conformity even if this goes against one's private beliefs. Indeed self-appointed 'mind-guards' would censor and punish any indications of dissent. In short, everyone agrees with the group 'line' and no one is prepared to mention its flaws, however obvious these might be. In this way, illusion and delusion come to dominate the decision-making process.

These symptoms of groupthink, Janis argued, derived principally from high group cohesion along with poor group structures and high levels of external stress. As Janis himself wrote "the more amiability and esprit de corps among the members of a policy-making group, the greater is the danger that independent critical thinking will be replaced by groupthink, which is likely to result in irrational and dehumanizing actions against outgroups" (1972: p. 13).

It follows from this analysis that the best way to avoid groupthink – to achieve the successful outcome of the Cuban missile crisis rather than the failure of the Bay of Pigs – is to dismantle the group, or at least to weaken the ties between group members. Janis advocates various measures such as bringing in external advisors, creating divisions within the group, and challenging group norms, all of which are designed to counteract 'the we-feeling of solidarity' (1982: p. 7).

There are, however, a series of problems with this analysis. Indeed, some critics mischievously suggest that such is the discrepancy between the continuing academic popularity of the Janis analysis and the actual evidence for it (for reviews, see Aldag and Fuller, 1993; Park, 1990), that just about the only argument for groupthink is the behavior of the research community that has studied this phenomenon (Haslam et al., 2006). Indeed, Fuller and Aldag go so far as to state that "in fact, in no study have all results been consistent with the [groupthink] model" (1990: p. 167).

First of all, then, there is no indication that the various components of groupthink (in-group boosting, out-group denigration, and enforced consensus) form a reliable cluster (Tetlock et al., 1992). Second, there is inconsistent evidence as to whether cohesiveness is an antecedent of groupthink phenomena, especially uncritical conformity (e.g., Flowers, 1977; Leana, 1985). Third, groupthink processes can lead to good organizational decisions as much as bad ones (Peterson et al., 1998). Moreover, as Haslam et al. (2006) argue, lack of shared identity and group cohesion makes it more difficult for group members to maintain the commitment necessary to drive *any* decision to success – especially in the face of opposition by out-groups.

In combination, these various findings point to two important conclusions. The first is that the ability to dissent, the willingness to consider discrepant information, the ways in which out-groups are treated and the nature (as well as the quality) of group decisions may have less to do with group psychology per se than with the specific norms and values associated with particular group identities. That is, whereas some groups may demand total deference to authority, others may be more accepting of dissent (Jetten and Hornsey, 2011; Packer, 2008). This is reflected in research that highlights how nationalism need not be a matter of 'my country right or wrong' but may take the form of critical attachment in which loyalty manifests itself as a willingness to identify and criticize national deficiencies (Roccas et al., 2006; Staub, 1997). Moreover, as studies in Israel, the United Kingdom, and the former Yugoslavia have shown, it is not identification with the group in and of itself which predicts denigration and support for the oppression of out-groups, but rather identification combined with a specific ideology of national glorification (Elcheroth and Reicher, 2014; Roccas et al., 2006). To cite Haslam et al. (2006), then: "although previous research has tended to see poor group decision making as a reflection of *psychological* deficiencies, there are strong grounds for questioning this assumption and arguing instead that problems of over-commitment are more *political* in nature" (p. 623, emphasis in the original).

We can also cite Haslam et al. (2006) in order to introduce the other conclusion. They ask: "how revolutionary movements (e.g. in science, politics and industry) would ever get off the ground if groups disavowed their own groupyness and were forever attentive to individual voices of doubt and dissent within their ranks" (p. 623). That is, to abandon groups is to leave the status quo inviolate. It is to leave existing tyrannies in place more than to create new ones. Such advice therefore serves less as part of the solution than as part of the problem of tyranny.

How, then, should we respond? The analysis provided thus far begins to suggest an alternative approach, one which is based on embracing rather than rejecting cohesive groups but which focuses on the content of group norms and hence on whether group power is used to create or challenge oppression in society. This analysis and these conclusions become clearer when we move from the consideration tyranny in intragroup processes to that of tyranny in intergroup processes.

Tyranny and Intergroup Process: Zimbardo's Stanford Prison Experiment

At just the same time as Irving Janis was developing his analysis of tyranny and oppression within groups, Philip Zimbardo was creating, in microcosm, his own system of tyranny and oppression between groups. What is more, his creation – the Stanford Prison Experiment (Haney et al., 1973; Zimbardo, 2007 – see also Zimbardo's Web site on the study: www.prisonexp.org) – has become, if anything, even better known than the work on groupthink both inside and beyond the academic world. Indeed, it is so well known that it only needs the briefest of outlines.

The study, which was scheduled to last for 2 weeks, began on 14 August 1971. Young men were randomly divided into the role of prisoner or guard. The prisoners were arrested in mock police raids and brought to the basement of the Stanford Psychology department which, for the purposes of the study, had been transformed into a simulated prison environment.

They had their heads shaved, were stripped naked, and made to change into short smocks without underwear, sprayed with what they were told was a delousing agent and then locked into small cells. They were overseen by guards – dressed in khaki shirts and trousers, carrying a whistle, a nightstick, and wearing reflective sunglasses – and under the authority of the 'prison superintendent,' Zimbardo himself.

What is best remembered about the study is the way in which the guards became increasingly abusive and dictatorial – taking pleasure in asserting their power, in degrading and humiliating the prisoners. As Zimbardo reported to Congressional Hearings just 2 months later:

> At the end of only six days we had to close down our mock prison because what we saw was frightening … human values were suspended, self-concepts were challenged, and the ugliest, most base, pathological side of human nature surfaced. We were horrified because we saw some boys ('guards') treat other boys as if they were despicable animals, taking pleasure in cruelty, while other boys ('prisoners') became servile, dehumanized robots.
>
> Zimbardo, 1971: p. 154

For Zimbardo, these findings testify to the power of the situation over the individual and show how "many people, perhaps the majority, can be made to do almost anything when put in psychologically compelling situations" (1971: p. 155). More specifically, Zimbardo argues that participants acted in terms of the role to which they had been assigned and that this happened without any intervention by the researchers:

> Participants had no prior training in how to play the randomly assigned roles. Each subject's prior societal learning of the meaning of prisons and the behavioural scripts associated with the oppositional roles of prisoner and guard was the sole source of guidance.
>
> Zimbardo, 2004: p. 39

Zimbardo's conclusion, then, is that human beings are helpless to resist the requirements and expectations placed upon them in groups. Thus, for instance, the tyrannical actions of his guards were: "emitted simply as a 'natural' consequence of being in the uniform of a 'guard' and asserting the power inherent in that role" (Haney et al., 1973: p. 12). In short, and as with Janis, the message is that group psychology is itself the problem. In line with his work on deindividuation processes (Zimbardo, 1969), Zimbardo contends that immersion among others subverts one's intellectual and moral sensibilities. It leaves one open to accepting influences and to acting in ways that one would normally shun. And where those influences are toxic, decent people will act with toxicity. Groups and power provide the 'compelling situations' that transform ordinary individuals into tyrants.

Zimbardo has applied this analysis to explain many instances of tyrannical behavior, such as the notorious abuses at the Abu Ghraib detention facility in Iraq. Indeed, he acted as an expert witness for the defense, arguing that the abusers were helpless to resist the requirements placed upon them. Staff Sergeant 'Chip' Frederick, accused of torturing detainees was not a 'bad apple,' Zimbardo maintained. Rather, he was a 'chip off the best block' who had been perverted by the 'bad barrel' in which he had been placed (Zimbardo, 2004: p. 344). However, Zimbardo's arguments were rejected in a letter from 49 psychologists to *The Observer* (official magazine of the *US Association for Psychological Science*) who claimed that he had misrepresented the scientific evidence in making his claims (Donnellan et al., 2007). They were also rejected by the judge in the case.

When it comes to looking for evidence that casts doubts on Zimbardo's role account, there is no need to look far. It can be found within the Stanford Prison Experiment itself. Thus, far from participants slipping helplessly into role, there are clear indications that participants resisted the position and the requirements placed upon them throughout the study (for detailed analyses, see Reicher and Haslam, 2006a; Haslam and Reicher, 2012b). For example, the prisoners rebelled from the start, and, if the extent of their rebellion declined over time, it was because Zimbardo actively intervened to achieve this end. He pulled one prisoner out of his cell, sought to recruit him as an informer, and led him to believe that he would not be able to leave the study even if he wanted to. But it is unclear if this impacted on resistance by getting the prisoners to act in role or, as Zimbardo suggests elsewhere, through inducing role confusion: that is, people no longer knew if they were participants in a study or truly imprisoned (Zimbardo, 1989). What is more, even after Zimbardo's intervention, prisoners continued to resist. What changed was the extent to which they supported each other in so doing – and once resistance was individualized, it was easier to contain.

Turning to Zimbardo's guards, the extent of resistance to role is even more striking. Again, Zimbardo himself acknowledges that many guards sought to be firm but fair and others actively sided with the prisoners. Only "about a third became tyrannical in their arbitrary use of power" (1971: p. 154). What is more, of this minority, the fame of the study largely hinges on the behavior of one guard, dubbed 'John Wayne' for his swagger and his aggression.

This raises the question of why this minority – and why this one individual – held sway over the other guards; why, that is, was he allowed to humiliate the prisoners without being questioned, let alone stopped? One answer is that he was seen to represent the values and the wishes of the prison authority, Philip Zimbardo. Certainly, Zimbardo did nothing to intervene or to suggest that abuse was inappropriate. Moreover, there is a growing body of testimony to suggest that Zimbardo and his fellow experimenters actively encouraged the guards to assert their power through use of the tools (e.g., chains, bags to put over the head) with which they had been provided. To cite Carlo Prescott, Zimbardo's chief advisor during the study, the guards were "merely doing what Zimbardo and others, myself included, encouraged them to do or frankly established as ground rules" (2005: p. 8). These ground rules were established from the very start. In particular, in Zimbardo's initial briefing to the guards (which can be seen in his own video of the study), he told them:

> You can create in the Prisoners feelings of boredom, a sense of fear to some degree, you can create a notion of arbitrariness, that their life is totally controlled by us, by the system, you, me … They can do nothing or say nothing that we don't permit. We're going to take

> away their individuality in various ways. In general what all this leads to is a sense of powerlessness.
>
> Zimbardo, 1989

All this is at odds with the claim that the guards acted autonomously and without any training. To borrow Banyard's elegant phrase: "it is not, as Zimbardo suggests, the Guards who wrote their own scripts on the blank canvas of the SPE, but Zimbardo who created the script of terror" (2007: p. 494).

Putting all these various criticisms together, it seems that conformity to role requirements was far from assured and that, to the extent that it did occur, it was as much a consequence of active leadership as of passive followership. On both grounds, the role account of tyranny between groups does not stand up. More generally, there is no support for the notion that there is something inherent in group psychology that makes us slaves to our roles within the group and prone to abuse those in other groups. Indeed, if we take seriously Zimbardo's suggestion that the reason why prisoner resistance was subdued has to do with the way he created role *confusion*, then we again are led to the idea that a coherent sense of group membership is necessary in order to challenge tyranny. This leads us to conclude that there is a need to rethink the relationship between group process, tyranny, and resistance.

Rethinking Groups and Tyranny: The BBC Prison Experiment

We have already seen how 1971 was an important year for social psychology. Janis was developing his groupthink analysis, Zimbardo was conducting his prison experiment, and, to complete the triad, Henri Tajfel and colleagues published their 'minimal group studies' (Tajfel et al., 1971). These studies, which addressed the minimal conditions of in-group bias, were the starting point for the development of social identity theory (Tajfel and Turner, 1979) and, subsequently, of self-categorization theory (Turner et al., 1987), which together form the social identity approach (for a review, see Reicher et al., 2010).

Over the ensuing decades, this tradition of work has transformed our understanding of group processes. Far from suggesting that groups make people less discriminating and liable to follow just any suggestion, the starting point of a social identity analysis is to argue that, when people categorize themselves in terms of their membership of any given social group (a social identification), they act in terms of the norms and values that characterize the group. Moreover, the fact that those who share the same social identification (e.g., 'we are all women') act in terms of the same shared norms/values, helps them to reach consensus, coordinate their actions, and thereby empowers them to achieve what they value (Haslam et al., 1998; Turner, 2005).

The question of when people act in terms of shared identity therefore becomes critical to understand when groups are empowered to reach their goals, and more particularly, when members of subordinate groups are able to challenge their oppressors (cf Haslam and Reicher, 2012a). Tajfel and Turner (1979) spell out some of those conditions. Notably, when a hierarchical social system restricts the upward mobility of subordinate group members (it is impermeable) and when that system is seen as both illegitimate and vulnerable (it is insecure), then they will act together to secure social change.

In 2001, 30 years after the Stanford Prison Experiment, the BBC Prison Experiment was run in order to investigate these ideas, again using a context in which ordinary people were randomly divided into guards and prisoners (see Reicher and Haslam, 2006a; for a full account of the study). While the study clearly drew on Zimbardo's paradigm, it differed in two crucial respects. First, the experimenters were careful not to position themselves alongside one group or the other, or to instruct the guards on how to behave (beyond telling them it was their job to make the prison run smoothly). Second, a number of theoretically based interventions were planned, based on the tenets of social identity theory. Most importantly, the prison system changed from being permeable at the start (prisoners had the prospect of 'promotion' to guard if they exhibited appropriate qualities) to being impermeable after a few days (prisoners were to stay prisoners however they behaved).

The results can be divided into two phases. The early phase provided strong support for a social identity approach to domination and resistance. First, as long as the system was permeable, the prisoners were divided on how to behave. They lacked shared social identity. Once the system became impermeable, however, the prisoners rapidly developed a shared sense of social identity. Second, shared identity enabled the prisoners to coordinate their actions, to support each other, and hence to become an effective unit. It empowered them to challenge the guards. By contrast, the guards lacked shared identity, failed to coordinate their actions, and indeed acted against each other thus canceling out each other's efforts. This undermined their effectiveness in meeting the challenge of the prisoners.

The combination of prisoner identity/coordination/empowerment and lack of guard identity/coordination/empowerment ultimately undermined the initial hierarchy. The prisoners broke into the guards' quarters and the prisoner–guard system collapsed. Together, the participants decided to inaugurate a new egalitarian system – a 'commune' in which all would be equal and work together. This ushered in the second phase of the study and provided new lessons, less in how people respond to an imposed system of inequality than in when and why they will create such a system for themselves.

At first, the Commune functioned well, with members working hard and working together. But there were dissenters. What is more, the dedicated 'Communards' were unwilling to use their authority to defend their system. In this context, they quickly became disenchanted and pessimistic about their ability to create a world rooted in their own values. The dissenters were aware of this and proposed an alternative, a new hierarchical system. As emblematic of the regime they proposed, these 'new guards' requested black uniforms, black berets, and black sunglasses – the iconography of fascism.

The study ended before this new system could be imposed. However the evidence suggests that, while the supporters of the Commune did not enthusiastically embrace it, their opposition was weakening and they certainly lacked the will to resist it. This is reflected not only in what they said and did but also in

the measures of authoritarianism that the researchers administered each day and that showed a steady rise as the Commune faltered. Paradoxically, then, the same people who had rejected, resisted, and overturned a relatively mild form of inequality at the study's start were on the brink of recreating a far more draconian system of inequality at the end.

These findings provide a root and branch challenge to traditional accounts of the psychology of tyranny. On the one hand, they suggest that it is not existence of cohesive groups which, in itself, leads to tyranny. Rather, cohesion gives group members the power to enact their norms and values even against the opposition of others. Far from removing their agency and their capacity to shape their own fate, it is as group members that most people achieve agency in the world (Reicher and Haslam, 2006b). But whether this is emancipatory or oppressive, progressive or toxic depends critically on the content of specific group identities and hence on the sorts of things they prescribe and value.

On the other hand, the findings, particularly from the second phase of the study, suggest that we should be more concerned with group failure than with group strength. When group members feel incapable of acting together to mold their own fate, they are far more likely to begin to shun democracy, to embrace strong leaders who will do things for them, and to accept extreme proposals from those leaders (Haslam and Reicher, 2007).

Conclusion

This analysis has centered on the question 'what is the role of group processes in the psychology of tyranny.' We have seen how the traditional answer has been to suggest that groups 'naturally' make people more slavish within the group and more tyrannical outside the group. The clear message is 'avoid groups' and certainly avoid the exercise of group power because groups and power are bad both for you and society. We have looked at the evidence for this widely disseminated viewpoint and found it wanting. We have also presented alternative evidence pointing to a very different analysis. This suggests that groups provide the basis for overcoming existing tyrannies and that the failure of groups is what allows such tyrannies to be established. The message here is that we should embrace groups with democratic and humane values and that we should use group power in order to defend these values. In short, the traditional psychology of tyranny is not simply wrong, it is dangerously wrong. It does not simply provide a misleading analysis of tyranny, whereas it gives advice that makes tyranny more (not less) likely.

There was a telling moment early on in the BBC Prison Study when the guards were reflecting on their uniforms, resources, and power. Without knowing the name of Zimbardo they expressed what has, by now, become a cultural commonplace: put the uniform on the man (or woman) and he (or she) will become a tyrant. So they shunned their uniform, resources, and power. Equally, later on during the Commune, several of the same people, and for precisely the same reasons, avoided using the power of this group against those who wanted to undermine their values. The irony, as we have seen, is that their very desire not to be tyrants created the conditions for a slide into tyranny. It is this that explains the paradox whereby those who rejected mild inequalities came to accept harsh tyranny. And, in addition to the theoretical reasons, this is why we need to reject the traditional psychology of tyranny.

Uncertainty: History of the Concept

Joshua Wakeham, University of Alabama, Tuscaloosa, AL, USA

Abstract

This article explores the various understandings of the concept of uncertainty in the social sciences. First, it examines the idea of uncertainty and related concepts. Then, it explores the use of the concept in economics, psychology, and sociology.

Within the social sciences, the concept of uncertainty has long been of interest, particularly in areas concerned with decision-making and knowledge. In very broad terms, uncertainty occurs at the limits of knowledge. In those social sciences that take an information-processing perspective on the problem of knowledge and cognition, such as economics, organizational studies, and some parts of psychology, some might describe uncertainty as a fundamental problem, even in places where it is not explicitly discussed. Uncertainty lurks in the background of any seemingly rational decision that is of interest to social scientists. A lack of certainty about the outcome of any action colors the way individuals or groups evaluate the world and their choices. Yet this is not the only understanding of the concept of uncertainty. One can find references to the problem of uncertainty – and related concepts – scattered throughout economics, psychology, sociology, anthropology, and related subfields. Both across and within the social science disciplines, there are differing understandings of the concept of uncertainty, as well as differing interpretations of its significance for social behavior and social science.

In order to better illuminate the history of the concept of uncertainty in the social sciences, this article sets out to do two things. First, it provides some conceptual discussion of uncertainty. Second, it provides historical overviews of the concept of uncertainty in each of the social sciences.

Conceptual Considerations

The Dimensions of Uncertainty

Broadly speaking, uncertainty refers to an epistemic state at the limits of knowledge. It concerns what is known or believed without certainty. It also concerns what is not known. If being certain means having clarity with regard to the truth, then being uncertain means having an obscured view of the truth. The problem of uncertainty points not only to the limits of what any individual might know, but also to the ultimate limits of what is knowable.

To put it another way, there are subjective and objective dimensions to uncertainty (Tannert et al., 2007). First, there are the subjective dimensions of uncertainty. An individual may experience uncertainty with regard to his or her own knowledge about some particular topic. Some experience or some piece of evidence might challenge an individual's once firmly held belief, causing them to have doubts about this belief. An individual may experience uncertainty about the possible outcome of some course of action. In important ways, this subjective, phenomenological experience of uncertainty is both cognitive and emotional. As such, it has obvious relevance to social behavior. There are questions of not only how the experience of uncertainty drives or influences behavior, but also how social context shapes the perception and experience of this cognitive and emotional uncertainty.

Second, there are the objective dimensions of uncertainty, which presume a world out there that is knowable only to a degree. Uncertainty, in this sense, is not necessarily something felt, but rather a feature of living in a complex world. It is useful to distinguish between epistemological and ontological uncertainty (Van Asselt and Rotmans, 2002). In the case of epistemological uncertainty, something that is potentially knowable remains unknown. Further research or searching for more information can reduce such uncertainty. In the case of ontological uncertainty, something remains unknown because it is ultimately unknowable. This may be due to the sheer complexity of the problem, the stochastic nature of the situation, or because natural processes obscure access to the relevant knowledge (such as time-obscuring access to historical knowledge). Thinking about uncertainty as an objective feature of the world is related to social scientific work at two levels. At the first level is the thinking about how other people encounter and deal with the uncertainty of the world around them. Problems of epistemological uncertainty, for example, and the practical problem of distinguishing between epistemological and ontological uncertainty are directly relevant to the social production of knowledge in the sciences, the law, medicine, business, and other venues. More broadly, how people manage ontological uncertainty, particularly as it relates to the complex social, political, technological, and economic systems that make up modernity, is of great interest for the social sciences. At the second level is the thinking about

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03175-5

how the social sciences themselves encounter uncertainty as a feature of the world. This has direct bearing on the limits of proposed models of human behavior, particularly on their predictive validity. Uncertainty, in this sense, is a technical problem that social scientists must account for in their models and explanations of human behavior.

Presumably, most of the time, the subjective experience of uncertainty and the reality of an uncertain world line up, so speaking of the uncertainty in the market or surrounding a particular policy decision or about some organizational strategy practically conflates these two analytic dimensions. Nonetheless, within the social sciences, researchers have emphasized different aspects of uncertainty, depending on their field and their research subject. This expanded view of uncertainty as having both subjective and objective dimensions provides a sufficiently broad framework for capturing the various ways the social sciences have used the term. However, it is also important to recognize that these different points of conceptual emphasis result in research projects that do not necessarily speak to one another.

Related Concepts

Within the social sciences, uncertainty is rarely considered on its own. It is often paired with other ideas related to challenges and problems in knowledge. This includes terms like risk, ambiguity, and ignorance. A brief discussion of how uncertainty has been associated with each of these terms is useful for further conceptual clarity.

Risk and Uncertainty

Uncertainty has most commonly been paired with risk in the social sciences. This is particularly true in economics, where it goes back to Knight's early work (1921), but it is also common in the more recent sociological work on risk and organizations, as well as work on the 'risk society' (Douglas and Wildavsky, 1983; Beck, 1992, 2009).

Risks are generally understood to be the *known* potential negative outcomes of a course of action. Risks include things like a loss on an investment, a nuclear plant having a meltdown, or the environmental and human health impact of widespread use of automobiles. A more technical understanding of risk typically includes some measure or guess of the probability of that negative-outcome happening multiplied by some measure of the presumed cost of that negative outcome. As risks are known potential outcomes, individuals or organizations presumably make efforts to mitigate or manage them, and avoid risks with costs that are too severe.

Uncertainty may be understood as the state of mind of someone deciding on a course of action without a clear outcome. In this subjective sense of the term, an uncertain individual consider the benefits and the risks, or potentially negative outcomes, of any course of action. Perceptions of costly risks are more likely to induce feelings of uncertainty about a particular course of action. However, when paired with risk, uncertainty has been more often understood in the more objective sense of the term.

If risks are known potential negative outcomes, uncertainty, in an objective sense, refers to the broader set of unknowns that may affect the course of action and its outcome. Risks, in theory, can be accounted for, but uncertainty cannot. A deeper critique of theories of risk management (in business, in management, or in other fields; or social sciences, such as economics), is that in the real world, the real probabilities of negative outcomes are never truly known, meaning that real uncertainty is more pervasive than any models of risk reveal (Taleb, 2010).

A final distinction between risk and uncertainty worth noting is the evaluative sense in which they are used. Risk bears a distinctly negative connotation. Objective uncertainty, by contrast, is neutral. Unknown factors may have a positive or negative effect on any course of action.

Ambiguity and Uncertainty

An ambiguous situation or problem is one that invites multiple interpretations. There is a lack of clarity about what it really is. Ambiguity has often been lumped together or even conflated with uncertainty. The amount of overlap between the two concepts, of course, depends on what definition one gives each idea.

Those who take information-processing approach to the problems of knowledge and cognition tend to define ambiguity, like uncertainty, more technically. Ambiguity, like uncertainty, has to do with missing information that is relevant to the outcome of an action (Galbraith, 1973; Frisch and Baron, 1988). Some economists, building on Ellsberg's paradox (Ellsberg, 1961), define ambiguity as uncertainty about the probability of possible outcomes rather than uncertainty about the outcome itself (Camerer and Weber, 1992; Dequech, 2000). Others in organizational studies (Schrader et al., 1993) have argued that in an ambiguous situation, the structure of the problem itself – i.e., the relationship between the potentially relevant variables – is unknown or unsettled, while in an uncertain situation, the structure of the problem is settled, but the value of the relevant variables is not. In these kinds of distinctions, one finds attempts to elucidate not just how the experience of ambiguity differs from uncertainty, but how dealing with ambiguity in order to solve a problem requires different strategies than dealing with uncertainty.

Ambiguity, conceived as a subjective phenomenon, has similarities with the experience of uncertainty. Encountering ambiguity is a troubling cognitive and emotional experience that pushes people to seek out clarity, even at an unconscious level. From experiments on perception in cognitive psychology (Hoffman, 1998) to sociological studies of culture (Zerubavel, 1993), social scientists have demonstrated how people, at the individual or collective level, appear motivated to resolve ambiguity, imposing a sense of clarity. Research using this conception of ambiguity tends to focus on the cognitive and social processes through which individuals and groups perceive and define problems and construct knowledge. Interpretive approaches to social science, particularly in anthropology and sociology, tend to focus on this kind of ambiguity, often conflating it with uncertainty. Arguably, the focus on social and cognitive processes and the production of knowledge rather than the outcomes of actions, where uncertainty has greater practical salience, may account for this emphasis on ambiguity and the underdeveloped sense of uncertainty as a distinctive notion.

Ignorance and Uncertainty

Some social scientists have also been interested in the larger problem of ignorance. Ignorance refers to the broad set of unknowns. Ignorance is of interest not only because it points to the limits of knowledge, but also because of its dynamic role in human affairs, as both a productive and destructive force (Gross, 2007). To that end, some have offered typologies that make distinctions between different kinds of ignorance. Merton (1987), for example, distinguishes between unrecognized and specified ignorance within scientific communities. Unrecognized ignorance refers to 'unknown unknowns' (Kerwin, 1993) or 'meta-ignorance' (Smithson, 1989) – ignorance of what one does not know. Specified ignorance refers to the acknowledged limitations of knowledge, which often drive the search for knowledge (in science and in other fields). Several related terms like *Nichtwissen*, nonknowledge, negative knowledge (Knorr-Cetina, 1999), and nescience (Simmel, 1906) are used in similar ways.

Smithson's taxonomy of ignorance (1989) makes multiple levels of distinction. The first level of distinction is between irrelevance and error. Things that are irrelevant are those that are deemed unworthy of further consideration. Error includes both distortions of information (confusion and inaccuracy) and incompleteness of information. Incompleteness is broken down into absence (e.g., missing piece of information) and uncertainty. Uncertainty includes vagueness, probability, and ambiguity. In this typology, uncertainty is thus a subtype of ignorance related to states where one has partial information.

Recent social scientific interest in the problem of ignorance tends to frame the social production of ignorance as process that is complementary to the production of knowledge (Proctor and Schiebinger, 2008). Cultural norms and social structures play a key role in placing and enforcing limits on what people know about the world around them. Within this framework, uncertainty is often treated as a political tool. For example, politically motivated propagandists use the scientific community's provisional sense of the truth to instill a false sense of uncertainty about the status of official scientific claims regarding things such as cigarette smoking or environmental degradation (Oreskes and Conway, 2011).

Uncertainty in the Social Sciences

Uncertainty in Economics

Of all the social sciences, economics has given the most attention to the concept of uncertainty. Given economics' interest in successfully modeling rational action, uncertainty poses a real problem. Uncertainty, as either an objective or subjective phenomenon, challenges many of the basic assumptions of such modeling efforts. The history of the concept of uncertainty in economics is very much one of attempting to 'tame and domesticate uncertainty' (Quiggin, 2009, p. 195).

For uncertainty in economics, 1921 was an important year. Both British economist John Maynard Keynes and American economist Frank M. Knight published books that dealt, in part, with the problem of uncertainty. In his *Treatise on Probability*, Keynes (1921) lays out an argument about demonstrating logical relationships between two propositions based on both a subjective probabilistic assessment of certainty in one's belief and the accuracy of that belief. While some relationships between two propositions can be established probabilistically, there are some instances where no numerical relationship can be established. Keynes considers these instances to reflect a kind of fundamental uncertainty about the world (Lawson, 1985; Dequech, 2000). Knight's *Risk, Uncertainty, and Profit* (1921) offers a basic definitional distinction between risk and uncertainty. Risk is measurable. The probabilities of the various outcomes are known. Uncertainty refers to those unknowns that cannot be quantified or measured. For both Keynes and Knight, the looming uncertainty of the world also explains some seemingly irrational social behavior (for Keynes, reliance on conventional thinking in the face of long-term uncertainty; for Knight, development of large, hierarchical organizations), as such behaviors have formed to help deal with or manage it. Keynes and Knight's similar understandings of uncertainty had influence on the post-Keynesian and Austrian schools of economics, respectively, but really failed to take hold in mainstream economics despite being cited often (Kelsey and Quiggin, 1992).

Uncertainty as an inescapable, objective feature of the world cannot effectively accounted for in traditional economic models, so most economists ignored or abandoned these particular definitions of uncertainty, treating them as heterodox. Instead, alternative understandings of uncertainty as a subjective phenomenon became more prominent. Being able to incorporate subjective estimates of probability – expressed or revealed – without regard to their accuracy (that is, essentially ignoring whether these estimates reflected objective features of the world) into economic models was a key. This is where development of expected utility theory comes in. Von Neumann and Morgenstern (1944) demonstrated that people evaluate outcomes by their expected utility – and that expected utility was subject to variation. This allowed economists to explain why people were often risk averse under conditions of uncertainty. This model influenced several lines of work, including game theory and several variations on the expected utility model. This includes Savage's (1954) work deriving subjective probabilities and expected utility from people's preferences, as well as Arrow and Debreau's (1954) demonstration of 'sufficient conditions' – namely, market completeness, or a market in which all future outcomes are accounted for by assuming a 'frictionless' market for all current goods – "for the existence of general equilibrium … under conditions of uncertainty" (Quiggin, 2009, p. 196). In what would become the prevailing microeconomic model, this meant that uncertainty, as it was conceived, could be effectively accounted for. Much attention turned to developing ways to better account for subjective probabilities in the models, such as Bayesian approaches (Hirshleifer and Riley, 1992), or variations on expected utility theory like rank-dependent expected utility theory (Kelsey and Quiggin, 1992).

Since the 1970s, a growing body of empirical findings has shown that people consistently violated the predictions of the expected utility theory. In particular, the work of psychologists Daniel Kahneman and Amos Tversky and their collaborators (Kahneman and Tversky, 1979; Kahneman et al., 1982; Tversky and Kahneman, 1992) demonstrated that under conditions of risk and uncertainty, people violated the predictions of the

expected utility model, but in consistent ways. In place of expected utility theory, they propose prospect theory, which takes into account the psychological dimensions of decision making. Prospect theory breaks choices down into two phases: editing/framing and evaluation. In the editing/framing phrase, people simplify available options and outcomes through a variety of heuristics, or cognitive shortcuts, which are determined by the context or formulation of the problem. Such editing or framing makes the evaluation phase easier. During this phase, people evaluate the outcomes or prospects of decision, following several psychological rules, such as using one's starting position to judge gains or losses, overweighing small probabilities or underweighing large probabilities depending on the risks, and loss aversion. The key lesson from all of this is that under conditions of uncertainty, people's behavior is not consistent with the rational actor model, but they do behave in relatively predictable ways. Essentially, people's minds draw on even the flimsiest pieces of evidence from the context in order to impose a subjective sense of certainty in a situation with objective uncertainty. At times, this leads people to overestimate the potential costs and underestimate the benefits (or vice versa) of such risky decisions. This work, of course, contributed directly to the development of the new fields, behavioral economics and behavioral finance.

These developments in the field of economics, along with the Great Recession of 2008, have led some (e.g., Taleb, 2010) to question the wisdom of economics effectively bracketing off the problem of objective uncertainty. However, the problem of effectively modeling or theorizing about unforeseen events and other exogenous shocks to economic markets still remains.

Uncertainty in Psychology

Uncertainty, usually as a subjective experience, often lingers in the background of various theories in psychology. Psychologists have connected uncertainty to the concepts of personality, emotion, and cognition, and the problem of decision making. Although work with these concepts often interacts, they map roughly onto the three distinct normative approaches to the problem of uncertainty that Smithson (2009) identifies.

The first approach comes out of the politicized psychoanalytic tradition of the mid-twentieth century. Tolerance of ambiguity and uncertainty are taken as signs of a positive, well-adjusted personality type, whereas intolerance of such epistemic conditions is often taken as signs of an authoritarian personality (Adorno et al., 1950). While the politics of such an approach have largely been toned down, interest in the concept of personality and relationship to the psychological experience of uncertainty have persisted. At the heart of this research is the idea that there are measurable differences in how individuals respond to uncertainty (Sorrentino et al., 1984; Sorrentino and Short, 1986; Sorrentino and Roney, 2000). Freeston et al. (1994) even developed an Intolerance for Uncertainty scale to measure such individual variation. Differences in tolerance for uncertainty are in turn measured against other psychometric data, including now widely accepted 'big five' measures of personality – openness, conscientiousness, extraversion, agreeableness, and neuroticism (Berenbaum et al., 2008). Even within this more recent work, a lack of tolerance for uncertainty – as an inevitable fact of life – is seen as potentially problematic from the individual psychological point of view.

The second approach to uncertainty focuses the cognitive, emotional, and physiological effects of 'uncertainty, unpredictability, and uncontrollability' (Smithson, 2009, p. 206). Uncertainty, in this sense, is a generally experienced problem. As such, it may even be a variable induced in laboratory settings. In such research, psychologists typically assume that uncertainty induces psychological distress or strain, including anxiety and motivation to seek certainty. For example, Berger and Calabrese (1975) put forth an 'uncertainty reduction theory' of social interaction and communication, arguing that in the initial stages of successful social interaction depends on reducing uncertainty among participants. Social psychologists have been interested in not only how uncertainty affects social interaction and communication (Gao and Gudykunst, 1990), but also social judgment and evaluation (van de Boss 2001, 2009). Recent work in neuroscience and cognitive psychology suggests that the drive for certainty works even at an unconscious level (Burton, 2008). The general lesson is that the experience of uncertainty often drives people into behaviors and beliefs that are potentially problematic because of an underlying cognitive and/or emotional need for certainty. Wilson et al. (2005) have challenged this largely negative assessment of uncertainty, demonstrating that the drive for certainty sometimes lessens the positive emotional experience of a positive event and that uncertainty about a positive event can lengthen the experience of positive emotions.

The third approach to uncertainty that Smithson identifies comes from research focused on decision making. This approach takes an information-processing perspective on cognition (Smithson, 1989). It is often found in cognitive psychology, but it is also related to other approaches to decision-making outside of psychology, including organizational studies, economics, and behavioral economics. Kanheman and Tversky's (1982) work is probably the best example of this approach. Researchers taking this approach tend to treat uncertainty like economists do, often conflating it with notions of probability or risk that can be accounted for in models of decision-making. The central concern is understanding and identifying cognitive biases and heuristics that people rely on when making decisions under conditions of uncertainty.

Uncertainty in Sociology

Considerations of uncertainty figure less prominently within the field of sociology. There are some areas, however, where the problem of uncertainty garners some explicit attention. In particular, in the field of organizational studies and in the social theoretical work on risk culture and society.

Organizational Studies

Organizational sociologists, and others under the broader umbrella of organizational studies, have long been interested in how uncertainty drives organizational behavior. The problem is, like in the other social sciences, the term uncertainty has often been used to refer to slightly different things. For example, of general interest is the uncertainty an organization faces in its task environment, yet environmental uncertainty has been conceived of as a state or an objective feature of

the world, as largely a matter of the perception of organizational actors, or having to do with the unknown effects of an action, or the unknown responses of the environment (Milliken, 1987). Because of such differences in understanding the concept, scholars have used the problem of uncertainty to account for an array of organizational behaviors.

The Carnegie School's early work on the cognitive-behavioral approach to organizational decision making, for example, focuses on the ways in which practical limits constrain or bound rational behavior (March and Simon [1958]1993). In the face of uncertainty, organizational actors often rely on standardization of behavior and responses (Cyert and March [1964]1992). Uncertainty thus contributes to the kind of suboptimal, bounded rationality observed in organizational decisions.

Uncertainty has also played a central role in the work on organizational design (Thompson, 1967; Lawrence and Lorsch 1967; Galbraith, 1973). Organizations cannot have full knowledge of their environment, so they must anticipate the unforeseen. One of the goals in organizational design is not necessarily to eliminate uncertainty (this is impossible), but to cope with it. This means not only paying attention to various sources of information (through the division of labor or specialization), but also designing an organization that is responsive to unanticipated information (through the successful integration or coordination of the parts). Attempting to cope with such uncertainty has been invoked to explain macrolevel organizational behaviors from a wide array of theoretical perspectives, including population ecology (Hannan and Freeman, 1977), resource dependency theory (Pfeffer and Salancik, 1978), and neoinstitutionalism (DiMaggio and Powell, 1983). Uncertainty, as either an objective feature of the environment or as a subjective perception of key organizational actors, can thus possibly explain differences in organizations across environment (more or less certain), as well as seemingly irrational or inefficient organizational behaviors and forms.

Beyond theories of organizations, the problem of uncertainty also plays a central role in the practical considerations of the literature on organizations operating in high-risk environments. The complexity of both technologies and large organizations make accurate assessment of the situations, actions, or consequences more difficult, if not impossible. With the threat of serious human and environmental costs for being wrong, managing risks and uncertainty is paramount. In his normal accident theory, Perrow ([1984]1999) argues that major disasters are an inevitable by-product of working under such epistemic conditions, so some high technological endeavors should be abandoned. In contrast, drawing on cases of successful organizational management of high-risk endeavors, the high-reliability organization theory out of Berkeley (Weick, 1987; Roberts, 1989) proposes that uncertainties and risks can be effectively managed with the right kind of management, organizational culture, and approach to teamwork and organizational learning and knowledge. Arguably, what separates these two different approaches to risk management is an assessment of the nature of uncertainty and our ability or inability to anticipate problems. In the high-reliability approach and in the broader literature on organizational risk management, one finds an understandable focus on preventing foreseeable mistakes and disasters. This places more focus on epistemological uncertainty. Perrow's more cautious approach places greater emphasis on the idea of ontological uncertainty – that is, there are things that are going to happen that could not be predicted.

Risk Culture and Society

The other area within sociology where the concept of uncertainty receives some explicit attention is in the social theoretical work concerned with the role of risk in modernity. Within this area of research, there has been emphasis on both the cultural and structural elements related to problems of risk. Douglas and Wildavsky's (1983) work on the culture of risk explores how perceptions of risk are tied to cultural ideals about what constitutes a good society. Fears and concerns about certain dangers do not necessarily reflect real risks, but rather culturally framed anxieties embedded within a particular social organization. More recently, Cerulo (2006) argues that culture plays a role in preventing people from anticipating the worst possible outcomes, skewing their perceptions to be overly optimistic. While this work emphasizes the problem of risk perception, the problem of uncertainty looms in the background. Culture shapes what areas of uncertainty receive more attention within a given social context, and thus, what areas of uncertainty people may fail to see coming.

Beck (1992, 2009) argues that one of the hallmarks of the postindustrial, globalized world is the unequal distribution of risks and hazards. Scientific and technological advances have brought with them the potential for untold human and environmental costs; yet those costs are not born out equally, especially in a globalized economy. This political dynamic, in effect, means that the powerful are able to minimize negative uncertainties in their lives, while those on the bottom have lives exposed to even more uncertainty.

Conclusion

The concept of uncertainty has had a varied, if somewhat inconsistent, history in the social sciences. At the heart of the matter is a conceptual confusion. Is uncertainty a characteristic of the knowledge itself or a characteristic of the knower? For better or worse, the social sciences have treated it as both. Uncertainty refers to an inevitable feature of the chaotic, unpredictable world, yet it also refers to a psychological state or phenomenological experience. How uncertainty has been conceived of in the social sciences depends on the agenda, methods, and theoretical assumptions of the researcher. Economists, for example, turned away from the idea of uncertainty as a kind of fundamental unpredictability because it essentially stands outside of the models and thus, the basic assumptions of economists. Uncertainty as a subjective experience holds greater sway in psychology and sociology because it is seen as a fundamental driver for an array of seemingly nonrational individual and collective behaviors. Yet this drive for certainty in an uncertain world does not eliminate the intrusion of unpredictable events in human affairs.

The lack of conceptual clarity and consistency does not undermine the importance of this idea to the social sciences. Rather it points to the challenges and the potential intellectual richness of working at the limits of human knowledge.

Unconscious: History of the Concept

Donald Levy, City University of New York, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The history of the concept of the unconscious in western thought will be discussed here in three phases of its development: 1. from as early as the sixth century BCE to the seventeenth century, when the concept was not usually distinguished from other, wholly metaphysical concepts in which it was embedded; 2. the beginning of the attempt, under the influence of Descartes, to distinguish the concept of the unconscious from its metaphysical moorings and to submit it to scientific examination; 3. the modern period, in which the concept is very commonly assumed by researchers in the social sciences despite doubts by some about whether the concept's separation from its metaphysical origins is, or ever can be, complete.

Metaphysical Beginnings

The idea that people are sometimes unaware of their own mental processes while these are going on, and may even be incapable of later retrieving them introspectively, has had a long life of its own, independent of and prior to its uses in modern experimental psychology, psychoanalysis, cognitive science, and linguistics. However, the idea's early occurrences do not appear tagged by a single term translatable as 'the Unconscious'; rather, the idea commonly occurs as a corollary of (1) the rationalist doctrine of innate ideas, and more broadly, of (2) the even more ancient idea of the microcosm, the traditional world view according to which each mind contains the universe, in miniature, within itself (Levy, 1967). Since the microcosm concept can be thought of, at least in part, as the view that all ideas are innate, the rationalist doctrine, for example, of Descartes, for whom only some ideas, e.g., of God, or of thought, are innate, is implied by, but does not imply the microcosm view.

Since, presumably, human subjects are never consciously aware of having all ideas within their minds, the concept of the unconscious is implicit in the idea of the microcosm; and to the extent that one might never consciously reflect on (what Descartes meant by) the idea of God or of thought, the concept of the unconscious is implicit in the doctrine of innate ideas, as well. However, rationalists often accepted the microcosm model, too, as for example, Leibniz, who writes of souls that they are 'perpetual living mirrors', each representative of the entire universe; and Plato, who used the example of a young slave untrained in geometry, led only by questioning to the discovery of a mathematical truth, to show the boy in the process of recovering the knowledge from within himself, where the possibility of this recovery of knowledge (*Meno*, 85D, 4–8), which Plato called recollection (*anamnesis*), rests on the claim that "…as all nature is akin, and the soul has learned all things, there is no reason why we should not, by remembering but one single thing…discover everything else" (*Meno*, 81C, 10-D, 4). Since neither Plato nor Leibniz meant to say that human subjects could consciously experience themselves 'mirroring' the universe or consciously recall having known the recovered mathematical truth at some earlier time, the prototype of the concept of the unconscious implicitly employed by them is a thoroughly metaphysical one.

Descartes and the Beginning of Scientific Scrutiny

Descartes's views require separate comment, since, unlike Plato and Leibniz, he had no explicit attachment to the microcosm concept; yet although he had no difficulty with the existence of unconscious mental states insofar as his doctrine of innate ideas implied them (Cottingham, 1998), he has nevertheless gained the reputation of having defined them out of existence as a consequence of his mind–body dualism and his supposed identification of conscious awareness as the essential attribute of mind. L.L. Whyte goes so far as to write, "Descartes … by his definition of mind as awareness, may be said to have provoked as reaction, the European discovery of the unconscious mind … Descartes … had no clear conception of the unconscious mind, for to him all that is unconscious is physiological" (Whyte, 1962: p. 80).

But it is thought, not awareness that Descartes defines as essential to mind (*Meditation II*), and Descartes takes seriously the possibility, concerning his ideas of the external world, that there is some "faculty not yet fully known to me, which produces these ideas without any assistance from external things; this is, after all, just how I have always thought ideas are produced in me when I am dreaming" (*Meditation III*). Such a faculty in him, by implication unconsciously active, apparently would need an intellectual substance to inhere in (*Meditation VI*), so it cannot, presumably, be purely physiological in nature. What finally persuades Descartes that such a deceptive and unconsciously acting mental faculty does not exist is not the thought that the idea of it is incoherent in itself (as would be natural if his view were as Whyte supposed), but rather that once God's existence has been proved, the existence of that faculty is incompatible with God's perfect goodness (*Meditation V*).

What it was in Descartes's philosophy capable of provoking the somewhat desperate efforts to defend the as yet unnamed (Whyte, 1962: pp. 25, 60) concept of the unconscious against him can more properly be found in his rejection of the comforts of the microcosm model, and his insistence on accepting as true only things that are clearly and distinctly perceived, things for which there are 'sure signs' (*Meditation I*). For when such a standard is applied to the concept of the unconscious, its defenders as well as its detractors are at least temporarily at a loss, since no-one then knew, nor is there complete consensus even now, as to where the defining line

separating conscious from other mental states is to be drawn. How exactly it can be proved that an unconscious part of the mind exists in reality, i.e., that it is more than a mere conceptual possibility (if even that), and what sure signs ought to be required of specific contents in it, remain subjects of debate. The contrast on these points with the conscious mind and its states appears quite stark. It was Descartes who first made necessary the project of attempting to separate the concept of the unconscious from the metaphysical moorings that had until that time shrouded it from scrutiny. The concept of the unconscious was itself about to enter consciousness. The search was on for its manifestations in empirical phenomena that could be examined in a scientific way.

The Modern Period

By the end of the nineteenth century, a wide range of psychological phenomena had been identified as seeming to need unconscious mental activity for their explanation: ordinary perception and habit formation, hypnosis and posthypnotic suggestion, dreaming and neurotic symptom formation, to name a few. According to William James (1890/1983), however, all such 'proofs' of the existence of the unconscious must fail, since the very idea of the unconscious mind is an 'unintelligible and fantastical' notion, and more parsimonious explanations of the phenomena in question are in all cases available, e.g., explanations in terms merely of (1) "brain-processes to which no ideation seems attached," (2) "perceptions and volitions…performed consciously, only so quickly and inattentively that no *memory* of them remains," or (3) 'split-off' consciousness, without any reference to unconscious mental activity having to be invoked.

By the end of the twentieth century, the range of psychological phenomena offered in support of the concept of the unconscious had expanded to include language acquisition and 'subliminal perception', 'blindsight', and cognitive dissonance and self-perception attribution processes (Nisbett and Wilson, 1977; Reber, 1993). However, skeptics have continued to doubt the existence of unconscious mental activity entirely, for reasons roughly similar to those laid down by James, though with more sophisticated arguments (Searle, 1992; Strawson, 1994).

There is here an evident lack of prior agreement about what conditions a phenomenon must meet for it to be a genuine instance of unconscious mental activity; one side of the debate assumes that more (and more novel) examples are needed to make their case, while the other (minority) side is already committed to the view that no possible example can succeed. At least it can be said of those who use the sorts of cases mentioned to support the existence of unconscious mental activity that they usually agree about what criteria determine the contents of the unconscious in any given case, and of what those contents are; there is, e.g., no dispute among them about what stimulus is unconsciously perceived in any given subliminal perception experiment, or what forgotten order the subject is obeying in posthypnotic suggestion, even if there are many questions about the way these stimuli are unconsciously processed.

By contrast, the psychoanalytic evidence raises different problems on this point, since there is no agreement concerning what Freud thought the criterion of truth in psychoanalysis is, and of what the consequences of adopting one criterion or another would be. It is widely supposed (e.g., by Grünbaum, 1984; Rey, 1998) that Freud thought therapeutic success is the only (or best) evidence of the correctness of psychoanalytic interpretations. The acceptance of such a criterion of correctness seems to leave Freud vulnerable to the well-known criticism that therapeutic success could as easily be due to suggestion or placebo effects as to interpretive truth. By contrast, Wittgenstein (1966; Levy, 1996) attributes to Freud the view that assent by the subject of an interpretation is ultimately the sole, or main criterion of its correctness. Which criterion Freud accepted, and which he ought to have accepted, are questions impossible to settle here; however, in favor of the assent criterion as the answer to both questions, it can be said first that the assent criterion seems more in accord with Freud's own most extensive discussion of the matter (Freud, 1937). Indeed, he even considers there the possibility that in some cases the mark of a true 'construction' (i.e., interpretation) will be that the patient's symptoms and general condition are not improved but rather are aggravated (Freud, 1937: p. 265). In addition, that criterion also allows interpretations to be true outside the therapeutic situation, where the danger of suggestion and placebo effects can more easily be avoided. Of course, in cross-cultural anthropological testing of non-individual psychoanalytic hypotheses (e.g., on the Oedipus complex, Whiting et al., 1958; Stephens, 1962; Spiro, 1982), neither the assent nor therapeutic success criterion is directly applicable. Finally, for Freud, very generally, it is wishes and ideas, not desires an beliefs, that inhabit the psychoanalytic (i.e., repressed) unconscious (Freud, 1893: p. 251, 1895: p. 10, n1, 1915a: p. 152, 1915b: p. 178). However, ideas and wishes, whether conscious or unconscious, lack the tight connection with behavior to be found in desire and belief; in many cases at least, it is plausible to say that a subject's ideas and wishes are ascertainable only by way of the assent and self-ascription the subject provides, whereas the comparable claim about desires and beliefs (i.e., when these are combined), would have very little plausibility. This provides further evidence that Freud accepted the assent criterion for individual interpretations, after all. Regardless of which criterion for individual interpretations is accepted, the question remains whether unconscious ideas and wishes as referred to psychoanalytically provide genuine exceptions to James's requirements. Without trying to resolve this matter here, it should be noted that the presence or absence of a brain process cannot hinge on the assent of the person whose brain it is; so if the assent criterion were assumed, explanations of James's type (1) would be foreclosed. How, if at all, unconscious contents as psychoanalytically interpreted, might also elude his explanation types (2) and (3) remains to be seen. More broadly, whether psychoanalytic interpretations are capable of experimental testing, and how (if at all) to resolve the difficulties that arise when such testing is attempted are also unanswered questions (Edelson, 1984; Erdelyi, 1985; Erwin, 1996; Levy, 2004).

However, at no point were these or any other epistemological difficulties able to deter philosophical, artistic, and even scientific activity that rested on ideas of the unconscious mind (Ellenberger, 1970; Kandel, 2012). Beginning long before Freud's time, and continuing in the Romantic culture of

nineteenth century Europe right up to the present, such ideas have figured prominently in the philosophies of Hegel, Schopenhauer, and Nietzsche (Mills, 2002; Gardiner, 1967; Lehrer, 1994), in the musical, literary, and visual works and critical theories of many artists (Wintle, 1992; Abrams, 1953; Hopkins, 2004), and continue to be influential in modern critical practice (Tennenhouse, 1976; Fuller, 1988; Gabbard, 2001). Nevertheless, it is also true that from the end of the nineteenth century and for much of the century that followed, in the world of science and the academy, skepticism about the reality of unconscious mental activity and the intellectual legitimacy of even discussing it was widespread outside of psychoanalytic circles. Thus, such diverse thinkers as William James (1890/1983), Jean-Paul Sartre (1943), John Searle (1992), and Galen Strawson (1994) share a view that goes far beyond mere uncertainty about the matter, although both James and Sartre later altered their hostile stance (James, 1902: pp. 214–215; Sartre, 1959). Yet by the end of the twentieth century, the question was rarely raised, so general was the shift away from denying or doubting to conceding the existence of the unconscious, even if what was individually believed varied significantly, beyond the mere agreement concerning its existence. What explains this shift from rejecting to embracing the assumption of the unconscious is not obvious. Conceivably, ideas about the unconscious in the arts and in popular culture may have played a part. It seems unlikely that any direct influence from psychoanalysis alone is the whole explanation. Certainly, the decline of Behaviorism (Graham, 2010) and growing doubts concerning the presuppositions about verification on which it rested (Levy, 1996: pp. 83–127) contributed to the shift. But it was the rise of cognitive science and neuropsychology in the second half of the twentieth century that most clearly turned the tide. However, to say this is simply to raise the question in a different way; for given the background hostility in place before they appeared, why did these new hybrid disciplines with their openness to conceptions of unconscious mental activity arise in the first place? Perhaps at present the most that can be said with certainty is that on all sides non-psychoanalytic psychologists in their own work unwittingly began to echo James Strachey's observation about Freud that he "found that without making that assumption he was unable to explain or even to describe a large variety of phenomena which he came across. By making it, on the other hand, he found the way open to an immensely fertile region of fresh knowledge" (Freud, 1915b: Editor's Note 162).

This is not to say that Freud's very special conception of the unconscious had achieved canonical status beyond the sphere of psychoanalysis. According to Freud, the most basic distinction concerning the unconscious separates those unconscious mental processes that have been repressed from those that have not (Freud, 1915b: pp. 166, 172), and although he thought both types of unconscious processes are capable of acting on consciousness (Freud, 1915b: p. 168), it is only the repressed type that concerned him very much. Since researchers in cognitive science and neuropsychology rarely focus on repression if they even recognize its existence (but for exceptions see Ramachandran and Blakeslee, 1998; Ramachandran, 2011), for most purposes it is reasonable to treat Freud's dichotomy as one that is nearly universally subscribed to. The essence of repression, Freud remarks "…lies simply in turning something away, and keeping it at a distance, from the conscious" (Freud, 1915b: p. 147), but this claim by itself is not adequate to distinguish repression from, for example, the fully conscious refusal to attend to a thing simply because it is a distraction – which is not what he means. Repression was preceded in Freud's early work on hysteria by the idea of defense, and the relation between repression and defense remained tangled, perhaps fruitfully so, since unlike mere avoidance of distraction, defense is something we attempt only against perceived threats and attacks, which is much closer to Freud's idea, but still makes repression sound like something that occurs completely on the conscious level. The term 'repression' in a psychological (i.e., non-political) sense can be found before Freud and some authors have suggested possible sources for Freud's use of the term (on Herbart, e.g., see Jones, 1953: vol. I, p. 309; Andersson, 1962: pp. 116–117); nevertheless, "it was as a clinical *datum* that repression imposed itself from Freud's earliest treatment of hysterics onwards. Freud found that his patients did not have certain memories at their disposition, although these were perfectly vivid once they had been recalled" (Laplanche and Pontalis, 1973: p. 392). It might appear as if Freud was struggling to formulate this *datum* satisfactorily, but that does not seem to be the case. His theory of repression sees it as occurring in two phases, the first of which takes place on the border between the conscious (or 'preconscious') and unconscious (Freud, 1915b: p. 180), as his first use of the term 'repression' in print suggests "…it was a question of things which the patient wished to forget, and therefore intentionally repressed from his conscious thought and inhibited and suppressed" (Breuer and Freud, 1895: p. 10). If repression is a partly conscious mental act at its start, it does not stay that way, he thought. 'Repression proper', as he called the second phase of its development, involved the fully unconscious repressed idea, now out of conscious control, 'putting out derivatives' (Freud, 1915a: p. 149), forming associations with other ideas, taking on extreme, distorted forms of expression (Freud, 1915a), and exerting continuous pressure in the direction of the conscious by way of its derivatives against the force of repression (Freud, 1915a: p. 151). Freud could lay down no general rule governing the degree of distortion or remoteness from its source that an unconscious derivative needed if it is to successfully affect the 'delicate balancing' by which the resistance it faces in its pursuit of becoming conscious is controlled (Freud, 1915a: p. 150). The repression those derivatives are subjected to may not entirely succeed (Freud, 1915a: p. 153), Freud held. Such failure of repression is possible, he thought, because the idea and the emotions that are attached to it can undergo separate transformation when subjected to repression. If those emotions are transformed into conscious pain or anxiety even as the idea remains unconscious, the repression has failed. One such failure of repression, Freud thought, can be seen in neurotic symptoms, which are derivatives that mark, in action, a 'return of the repressed' to consciousness (Freud, 1915a: p. 154). Another failure of repression can be found in the verbal 'free associations' human subjects produce, which are derivatives of repressed ideas sufficiently distorted or far removed from their source to enable them to gain access to consciousness. These are 'substitute formations' (Freud, 1915a) by means of which the repressed idea can be consciously reconstituted, Freud thought (Freud, 1915a: p. 150). His obscure reference to the 'delicate

balancing' governing the success or failure of repression that unconscious derivatives encounter may allude to an unresolved problem in his conception of repression and symptom formation as well, for in his view neurotic symptoms "are the outcome of a conflict…The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides" (Freud, 1916–1917: pp. 358–359). Thus, for Freud, every symptom is a 'compromise-formation', a claim whose universality has been questioned (by Laplanche and Pontalis, 1973: p. 76) on the grounds that symptomatic phenomena are sometimes encountered clinically in which no compromise between defense and wish is apparent – instead, one or the other seems to dominate. However, according to Morris Eagle, in an assertion perhaps consistent with Freud's compromise-formation view of symptoms, we need to recognize that repression itself has both adaptive and maladaptive functions; "repression is both normal and pathogenic" (Eagle, 2002: p. 484).

The fundamental procedure for investigating the repressed unconscious, according to Freud, free association, requires the patient to 'abandon conscious purposive ideas' (Freud, 1900–1901: p. 531), that is, all goal-directed bodily and mental activity, while inhibiting as well attention to the social and practical constraints we impose on our actions when we consciously pursue goals of any kind. The requirement that all activity be suspended has the effect of releasing the mind from everything that normally works to distract it from itself. Then, the method of free association requires that voice must be given to all thoughts entering the mind, which means that considerations of politeness and social acceptability, for example, are suspended, as well as considerations of what is necessary or rational or appropriate in the solution of practical problems, whether physical or mental in nature. Thus, ideally, all inferring, planning, calculating, summarizing, organizing of one's thoughts is consciously inhibited. The ideas that then occur and which the patient gives voice to are 'free' insofar as they are presumably not governed by those social and practical constraints that we normally rely upon in regulating our conscious thinking and acting. However, since the ideas produced in that state have entered consciousness, but are also uncoupled from conscious activities, Freud viewed the ideas we then give voice to as derivatives ('substitute formations') of the repressed ideas which he identified as their source. Since such free associations have partially eluded the force of repression just by entering consciousness, they are not the repressed ideas themselves. But since those free associations are presumed to be detached from the patient's conscious mental or physical activity, their very freedom from connection to such activity allows them to be used as evidence of the repressed ideas from which they came, Freud inferred.

Is it realistic to suppose that anyone can totally suspend conscious purposive ideas as is, required for free association to lead to the recovery of repressed ideas? There is, perhaps, an element of benign deception practiced on the patient here; Freud writes "When I instruct a patient to abandon reflection of any kind and to tell me whatever comes into his head, I am relying firmly on the presumption that he will not be able to abandon the purposive ideas inherent in the treatment and I feel justified in inferring that what seem to be the most innocent and arbitrary things which he tells me are in fact related to his illness. There is another purposive idea of which the patient has no suspicion – one relating to myself" (Freud, 1900–1901: pp. 531–532). The 'deception' here is benign because it is easily practiced on oneself, as Freud himself had done, for example, in using free association to interpret his dreams to his own satisfaction; a shift in the focus of attention is needed here, where there is no treatment in question. So free association, in Freud's view, is a way of generating valuable new evidence that enables the gaps in our understanding of otherwise obscure mental occurrences to be filled.

But is it perhaps more than that? The idea that there is some kind of internal relationship, between the psychoanalytic project and the practice of free association is hard to avoid. It is fair to say that without the technique of free association and the new kind of evidence it summons up, Freud's belief that he had discovered a new method for *analyzing* dreams, jokes, slips, and neurotic symptoms would be very much harder to support. (Freud later added the choice of a profession, of a love-object and of a subject-matter by the creative artist to the list of things suitable for analytic interpretation.) For free association does seem to offer a way of breaking down any individual instance of each of these mental formations into parts and inferring – or ideally, recollecting – the unconscious origins of each, by applying free association to the results; the chain of associations may be long, but there is no reason to suppose it is interminable. The method seems to produce impressive results especially when applied to the interpretation of dreams, which is where Freud began to apply it almost as soon as it was suggested by one of his female patients in regard to her own symptoms. Of course, dreams, unlike symptoms are not normally involved in inhibiting or generating behavior in the way that symptoms often are, which means that inhibiting attention to the 'social and practical constraints' is easier with dreams than with symptoms.

By means of free association, we can temporarily and partially elude the distractions of normal life as well as the force of repression by which we disguise from ourselves the real nature of many of our conscious thoughts and actions. The task of the analyst would be unthinkably greater, if free association were impossible, as is usual with long-dead historical figures, although Freud thought Leonardo da Vinci was an exception about whom he could draw some interpretive inferences, precisely because Leonardo's private notebooks contain numerous drawings and jottings, including slips, which Freud thought could be treated as if they were free associations and analyzed as such (Freud, 1910). To see how valuable in the task of analysis is the evidence from living human beings provided by free association, let us imagine that some people responded to the request for them to free associate with puzzlement. That is, suppose that to them, having ideas while engaged in no conscious, purposive *activity*, whether physical or mental, were entirely empty – they never had such ideas to report, and were puzzled by our expectation that anyone ever did (dreams would therefore be beyond their experience). So although they told jokes, made slips, and exhibited neurotic symptoms, the only ideas they have ever had were ideas bearing on actions, e.g., what they could or should do when they became active; they seemed unable to even conceive of disengaging the having of conscious ideas from physical or mental purposive activity.

It is hard to see how such people (who would appear to us to be woefully deficient in imagination) could engage in free association, or how they could be psychoanalyzed; the best that could be managed in their case would apparently be to draw rough analogies between their actions and our own. On this view, then, free association would be integral to psychoanalysis since it would have to be seen as providing much more than merely collateral evidence for the truth of psychoanalytic interpretations; it would not be simply one heuristic device among others for exploring the repressed unconscious.

When free association is displayed in this way as in effect indispensable to the practice of, psychoanalysis, it then becomes possible to place psychoanalysis within a larger historical framework, one that embraces the psychological contributions of many diverse cultures, especially those of the 'Axial Age' as the period around 700 to 200 BCE in Europe, Asia, and the Middle East has come to be called. Developments within the Asian branch of that pivotal epoch, especially in the cultures of India and China, seem most relevant, given the striking similarities between psychoanalysis and the spiritual disciplines of that time and place. Prominent in all those disciplines was meditation in its various forms, and it is the similarities between free association and meditation that concern us, for in each case, the meditative technique was seen to be integral to the discipline, just as free association is integral to psychoanalysis. Furthermore, all such techniques share a common starting point, i.e., the intentional inhibition of goal-directed activity, just as in free association, and the focusing of one's attention on the nature of that attention itself becomes the source of very different prescriptions concerning its use. These analogies and many more began to interest psychoanalysts in the second half of the twentieth century, and that interest has continued to grow, with no sign of stopping.

Any historical account of such techniques and their respective disciplines would have to begin with Yoga, which shares inhibited action, both mental and physical, as its starting point with free association in psychoanalysis. In this respect, it is like the Alexander Technique, another modern discipline that focuses on correction and improvement of the use of the body (Alexander, 1988). The role of inhibited action in these disciplines as a heuristic device for sensitizing the practitioner to the habitual distortions of posture and movement unwittingly acquired over a lifetime strongly resembles the role of such inhibition in free association, which can also be viewed as a practice whose purpose is sensitization. But Yoga in its original form was very different, and the relevance of that version of it to psychoanalysis is limited, since to start with Yoga seems to have consisted in concentrating attention in order to achieve a trance state of total oblivion, which was held to be the necessary condition for escaping from karma with its cycle of rebirths, and attaining oneness with Brahman, the universal Absolute (Wynne, 2007: p. 82). On that view, there would be little room for very much of an analogy with free association, although inhibiting attention to the constraints governing activity, which must be a part of the path to oblivion, is exactly what free association requires as well. Possibly ancient Yoga had hidden dimensions that would make a connection with psychoanalysis more evident than it is at present.

The inventor, or discoverer, of meditation in a form that does have direct connections to free association, was the Buddha, who self-consciously sought to replace the Yoga of his time with a very different practice, one no longer focused on attaining oblivion. Instead, self-observation and analysis is to be cultivated as a means to achieving Nirvana, the 'snuffing out' or cessation of 'grasping desire,' the kind of desire manifested, most prominently, in addictive behavior and the quest for revenge (Gombrich, 2009). Besides being a pioneer in psychology, the Buddha was a social reformer with a revolutionary moral agenda; thus, he defined Nirvana, which included release from the compulsion to repeat past habits, as requiring non-observance of all caste restrictions (Buddha, 1986, 2000). Of the many Asian Axial Age thinkers, the Buddha is certainly the one who has attracted the most attention from psychoanalysts (see, e.g., Epstein, 1995); as a consequence, it is impossible to deal here with even a small selection of them (but see Safran, 2003 for a representative sampling).

However, key ideas of other Axial Age thinkers, both Asian (e.g., Confucius and Lao Tzu) and non-Asian, have also been found relevant to psychoanalysis (Fingarette, 1963; Bion, 1994; Eigen, 2011). One of the main outstanding questions about the relation between psychoanalysis and all of these Axial Age thinkers is whether psychoanalysis is simply a revival of practices and ideas from that earlier creative period, or is instead a truly new development, and if it is something new, in what way? For example, the apparent absence of a social and political agenda in much contemporary psychoanalysis seems to mark a contrast with its Axial Age predecessors. Whether that absence, if it is real, is a source of strength or is instead a defect remains to be seen. Another dangling problem concerns Freud's espousal of determinism, which threatens to subvert the entire therapeutic project, according to A. MacIntyre, because if it is accepted, there will be no essential difference between "the suffering neurotic and the successfully analysed patient", since both are subject to the "omnipresent causation exerted upon conscious life by the unconscious" (MacIntyre, 2004: pp. 112–113). There is at present no generally accepted response to this problem, either within the psychoanalytic community or outside it.

This article is a revision of the previous edition article by W.J. Wilson, J.M. Quane and B.H. Rankin, volume 23, pp. 15945–15948, © 2001, Elsevier Ltd.

Abstract

The term 'underclass' came into wide use by academics, policymakers, and the press during the latter quarter of the twentieth century to refer a subset of the urban poor marked by their isolation in decaying ghettos of increasingly concentrated poverty, and their self-defeating behaviors in response to these conditions. Controversy followed, with critics challenging the term's racial and cultural implications, conceptual definition, and empirical measurement. Historical antecedents are found in the work of major political thinkers and propagandists such as Malthus, Marx, Bakunin, and Myrdal. The contentious debates of the last 30 years over the exact meaning and implications of the term diverted attention from the underlying phenomena of urban poverty, joblessness, and dependency. To the extent that the term is used today, it refers to groups who are structurally cut off from the pathways to social and economic mobility.

The controversial term 'underclass' has been used by both academics and the popular press to describe a subset of the poor. The controversy stems from a lack of agreement on the particular characteristics of the subset and the normative content of inclusion in the group. Moreover, the empirical strategies proposed to measure the size of the underclass were problematic and did not gain wide acceptance. In this article, we discuss the origins of the term, its conceptual definitions, attempts to measure the size of the underclass, and current usage of the term.

Historical Origins of the 'Underclass' Concept

As societies grapple with the problems of poverty, there is a long-standing practice of dividing the poor into those who are deserving of assistance and those who are not (Katz, 1989). The deserving poor are said to be destitute for reasons beyond their control, such as economic depressions or the death or disability of a breadwinner. In contrast, the undeserving poor are said to bring poverty upon themselves, by engaging in self-destructive behaviors and failing to embrace mainstream values. In colonial America, this was reflected in the distinction between poverty, 'an unavoidable evil,' in the words of Reverend Charles Burroughs preaching in 1834, and pauperism, "the consequence of willful error, of shameful indolence, of vicious habits" (Katz, 1989: p. 13).

Thomas Malthus, writing at the turn of the eighteenth century, expressed concern about what he saw as a 'redundant population.' "If we multiply too fast," he wrote in *An Essay on the Principle of Population* (1806), "we die miserably of poverty and contagious diseases" (Malthus, 1806; reprinted 1989: p. 88, cited in Morris, 1994: p. 10). Overpopulation, argued Malthus, was the result of early marriage, too many children, and too many children relative to life expectancy. It was the poor who suffered the most from overpopulation, and it was the poor who were least likely to understand the causes of their own poverty. "When the wages of labor are hardly sufficient to maintain two children, a man marries and has five or six. He finds himself miserably distressed," wrote Malthus, but, "the last person he would think of accusing is himself" (Malthus, 1806; reprinted 1989: p. 106, cited in Morris, 1994: p. 11). For Malthus, the problem was personal weakness in the face of natural passions and desires that require regulation, especially sexual behavior. The notion of moral restraint as a check on population growth and, therefore, the spread of poverty through a subculture of vice, is thus deeply implanted in attitudes toward the poor that locate the causes of immiseration and exclusion in the behavior of the immiserated rather than in the organization of economies or societies.

Ideas about social marginality and class exclusion as threats to social order expanded in the nineteenth century with the rise of industrialization, mass employment, and later, modern social science. In the *Eighteenth Brumaire of Louis Napoleon* (1852), Marx identified a 'dangerous class,' the *lumpen-proletariart*, to distinguish between revolutionary and reactionary strata or 'fractions' within the industrial working class. The *lumpen* were a rag-tag group of ruined refugees of the bourgeoisie, vagabonds, pimps, beggars, swindlers, pickpockets, and others of 'dubious means of subsistence and of dubious origin,' incapable of developing a class consciousness (Marx, 1963: p. 75). In Britain at this time, a related notion of a social 'residuum' emerged in debates over the extension of the suffrage. Welshman, for example, notes that in 1867, the radical Birmingham Minister of Parliament John Bright, in debating the merits of the Second Reform Act, argued for the enfranchisement of the respectable, skilled male working class, but also for the exclusion of a substrata of the unskilled and the 'feckless and criminal' poor "because they have no independence whatsoever," he said, and thus, were not worthy of the vote (Welshman, 2006: p. 7). Exclusion was achieved by legislation through the imposition of a modest householder income qualification.

It is a hallmark of the underclass idea that form its various early incarnations, it has been freighted with contentious political, social, and moral meaning. Contrary to Marx, for example, the influential nineteenth-century anarchist theorist Mikhail Bakunin located revolutionary potential among those who had been spared the harsh and degrading discipline of industrial work. Ideas about an 'industrious unemployed,' who

lost work as a result of upheaval and instability in the trade cycle, began to take hold as progress toward working-class enfranchisement in England unfolded. This can be seen in the emergence of scientific philanthropy in the form of the Charity Organization Society (COS) founded in London by Octavia Hill and Helen Bosanquet in 1869, and the associated movement of private charity societies that subsequently spread across Europe and the United States. Hill and other reformers in this movement believed that mere alms giving was not enough. What was needed was investigation and analysis of the deeper causes of poverty if dependency among the poor was to be averted. The COS introduced methods of modern records management, objective empirical investigative techniques that formed the early basis of social casework, and professional training of its 'visitors' to teach the deviant poor values of self-reliance, thrift, and hard work necessary to overcome the difficult hand they had been dealt. The COS did distinguish between the deserving and undeserving poor, but, importantly, a link had been made between economic cycles and the devastating consequences of unemployment, ideas that would reemerge among social scientists in the mid-twentieth century.

Gunner Myrdal (1963), often credited with being the first modern scholar to employ the underclass term, found that a growing population was unable to access employment or the skills and training necessary to participate in the regular labor market. Myrdal's concern, however, was principally with the effects of technological change on the workforce and chronic unemployment rather than the behavior of the poor. Myrdal believed that Americans were familiar with the causes of unemployment, but that the cultural emphasis on individualism and an optimistic belief in class mobility meant they had little understanding of how unemployment was trapping people at the bottom. Other scholars in the 1960s – such as Liebow (1967), Rainwater (1970), and Hannerz (1969) – wrote about a separate lower class culture, but they refrained from using the term 'underclass,' and poverty debates in the United States during this time were mostly consumed with Oscar Lewis's idea of a 'culture of poverty' (1959, 1969). Echoing Myrdal in one of the first scholarly treatments of the underclass in the modern period, Douglas G. Glasgow's *The Black Underclass: Poverty, Unemployment and the Entrapment of Ghetto Youth* likewise argued that "the underclass is distinguished from the lower class principally by its lack of mobility" (1980: p. 8). Whereas lower class status means you are on the bottom rung of the economic ladder, underclass status implies that the ladder is effectively unavailable to you. Entrapment in the underclass is driven by prolonged unemployment, inadequate education, and a "lack of connections to standardized institutions that act as feeder systems to the primary labor market" (Glasgow 1980: p. 7). The underclass is outside the regular channels of the class structure and, therefore, highly unlikely to be able to improve their position over time.

There was little more discussion of an underclass in academic circles until later in the 1970s, as the first troubling signs of the economic dislocation to come began to manifest in cities and communities facing plant closings, white flight, and government disinvestment. In the popular media, especially in the 1970s and 1980s, the term 'underclass' was used to describe the inner-city poor persons, often blacks, who exhibited any deviant or self-destructive behavior. The devastation wrought by the crack epidemic, the rapid rise in out-of-wedlock childbearing, and the surge in violent crime troubled academics, politicians, and the public. Vivid journalistic accounts of the harsh conditions of life in inner-city black ghettos (Auletta, 1982; Dash, 1989; Lemann, 1986a, 1986b; Wilkerson, 1987) emphasized crime, violence, drug use, dropping out of high-school, out-of-wedlock childbearing, and lack of connection to the formal labor market. Lemann emphasized increasing social disorganization in the black ghetto, beginning in the late 1960s, with the out-migration of a better-off black working and middle classes from the inner cities to the suburbs. The underclass, again, were trapped by unemployment in decaying cities left behind, their behavioral deviance an adaptation to their circumstances. This behavioral description of an urban underclass leads to assigning moral culpability for their poverty to those who participate in the ghetto lifestyle. "Underclass," argued Jacqueline Jones (1992: p. 9), "was but one more term used to label and objectify people believed to be morally dissolute and criminally inclined."

Popular and journalistic interest in a new underclass stimulated social science inquiry, as it had done in England a century before. William Julius Wilson's influential book, *The Truly Disadvantaged*, defined the underclass as those "who are outside the mainstream of the American occupational system" (Wilson, 1987: p. 8). This includes those who lack the training and skills to access available jobs and, therefore, experience long-term spells of unemployment or drop out of the labor force altogether. Wilson's work tied the emergence of the underclass to several distinct trends that came together in the inner-city to transform black ghettos. The inner-city black poor, who had always been segregated from whites, became increasingly segregated from the black middle-class due to expanded housing opportunities for economically successful blacks, depriving black ghettos of social capital, and increasing the social isolation of the ghetto poor. At the same time, deindustrialization and the suburbanization of job growth increased joblessness and reliance on alternative means of support, from public welfare to criminality. The result is a 'disproportionate concentration of the most disadvantaged segments of the urban black population,' which created a 'social *milieu*' that fostered low labor force attachment, out-of-wedlock childbearing, drug and alcohol use, and other social pathologies (Wilson, 1987: p. 58). Wilson's analysis addressed the growing divide between the behavior and lifestyle of the inner-city poor and the American mainstream. His analysis acknowledged the emergence of ghetto-specific patterns of behavior that were at variance with mainstream values, but he linked them to macrostructural transformations in the economy and the growing social isolation of the inner-city poor.

Critiques of the Underclass Concept

Wilson's work refocused liberal social science on the problem of urban poverty in the 1980s. It emphasized the devastating impact of broader changes in the American economy and unemployment on the black urban poor, but it also walked a fine line between cultural and structural explanations of poverty. Wilson did not explicitly reject the idea of a culture of poverty (Lewis, 1959, 1969), arguing that weight must be given

to culture, observed as behavior, because cultural practices reflect adaptation to structural conditions. Despite Wilson's efforts to keep the focus on macroeconomic change, his work sometimes was interpreted as an endorsement of the idea of the underclass as isolated from the mainstream by their values and behavior in ways that are damaging to their prospects of escaping the trap of 'ghetto culture' with its 'tangle of pathologies.' In response, the most vigorous criticism of the dominant concept of the underclass that emerged in the 1980s charged that framing the black urban poor as an underclass was supported empirically and marked a dangerous return to discredited notions of an 'undeserving poor' and a 'culture of poverty' as an explanation for their material deprivation.

One of the earliest critics of Wilson was Norman Fainstein (1987) who rejected Wilson's adoption of a language of class as an empirically unsupported means of falsely diminishing the importance of racial discrimination in explaining urban poverty. Fainstein also challenged the empirical validity and significance of the spatial mismatch hypothesis, an analysis relied on by underclass researchers to support their arguments that the inner-city poor were isolated socially (Fainstein, 1987, 1993). Adolph Reed joined Fainstein in criticizing the underclass concept as scientifically questionable and beyond that, as veiling racism in the sociology of the policy research community (Reed, 1990; see also Rosenthal, 1999; Bonilla-Silva, 2001; Feagin, 2001). Other scholars avoided analyzing the underlying attitudes or motivations of social scientists, but similarly found that Wilson ignored the salience of on-going racial discrimination as an explanation for increasingly concentrated poverty (Massey and Denton, 1993; Massey et al., 1994). Some further questioned whether the underclass met the definition of a class or represented a homogenous social grouping (Heisler, 1991; Herpin, 1993; Massey, 1993; Zelley, 1995; Wright, 1994; Martiniello, 1996; Marshall et al., 1996; Wacquant, 2008), and challenged the degree to which the urban poor, and specifically, inner-city blacks, were socially isolated (Oliver, 1988; Newman, 1992; Phillips, 2001) or collective adherents to morally repugnant values (Anderson, 1999).

More than any other scholar, Herbert Gans presented the most sustained critique of the underclass concept. In essays (1990, 1994) and a book, *The War Against the Poor* (1995), Gans argued that 'underclass' was simply a 'buzzword' for the undeserving poor and that 'the term has taken on so many connotations of undeservingness and blameworthiness that it has become hopelessly polluted in meaning, ideological overtone and implications, and should be dropped' (Gans, 1990: p. 272).

The debate, however, is not so much one of terminology, as it is Gans's deep concern with the effects on public opinion of the people so labeled and the policies that follow what for Gans is a pejorative misidentification of a social group. Gans argued that two novel elements in the Wilsonian conception of the underclass mark a departure from its more benign use by Myrdal and heighten the danger of separating groups from the rest of society by pointing selectively to their behavior. One is the term's racialized context, as the underclass is seen as almost entirely black and Hispanic, while racial minorities continue to face various forms of pernicious discrimination. The other is the elaboration of associated pathologies and antisocial behaviors that has the effect of inflaming public opinion and legitimizing a moral indictment of the poor. Moreover, observed behavioral patterns are assumed by most underclass researchers to be caused by norm violations rather than the conditions under which very poor people live. Methodological problems with measuring the underclass (discussed in the following section) are important to Gans's critique, but he goes further to warn of the consequences for civil liberties and democracy itself of a license to stigmatize and therefore scapegoat the disadvantaged.

Measurement Strategies

Ricketts and Sawhill (1988), working with a group of researchers at the Urban Institute, operationalized the underclass concept in a way that could be applied to census data so that national estimates of the phenomenon could be produced. Many of the elements of the conceptual definition of the underclass are not available within the census data, so it is inevitable that the operational definition for quantitative empirical work will be cruder than any particular theoretical conception of the underclass. They sought to identify "a subgroup … that engages in behaviors at variance with those of the mainstream" (Ricketts and Sawhill, 1988: p. 318). Their approach also had a geographic component, in that they identified underclass neighborhoods in which a high proportion of the residents engage in behaviors at variance with mainstream expectations. The neighborhood focus relates to the belief that when dysfunctional behaviors are concentrated, they become normative for the adults, and especially the children, growing up in these neighborhoods. Neighborhoods, proxied by census tracts in their analysis, were designated as underclass if they were simultaneously one standard deviation above the national mean on four characteristics: (1) the percentage of families with children headed by single females; (2) percentage of adult males whole worked fewer than 26 weeks or were not in the labor force; (3) percentage of households receiving public assistance; and (4) percentage of 16- to 19-year-olds not in school and not high-school graduates.

The Urban Institute underclass measure can be criticized on many grounds. For one thing, not all individuals who engage in underclass behaviors live in underclass neighborhoods and not all residents of underclass neighborhoods engage in underclass behaviors. Furthermore, Wilson (1988) criticized the measure on the ground that the second condition combined those who were not in the labor force (a choice) with those who had long spells of unemployment (an economic outcome). Even labor force participation is partly an outcome in the sense that discouraged workers withdraw from the labor market because they see no realistic prospect for employment. Hughes (1989) argued that the use of an underclass neighborhood threshold based on national norms rather than metropolitan norms was problematic, given regional differences in welfare benefit levels and macroeconomic conditions. He argued that the use of metropolitan norms, rather than national norms, would "focus on the concentration of deprivation within certain neighborhoods" rather than on differences in the four characteristics among metropolitan areas (Hughes, 1989: p. 192).

On the basis of 1980 means and standard deviations for the four indicators, Ricketts and Sawhill found that about 2.5 million (or about 1% of the US population) lived in the underclass areas. Virtually all the underclass tracts were in urban areas, disproportionately located in the older industrial cities, such as Newark, New York, and Baltimore. Residents of underclass areas were 59% black and 10% Hispanic. In comparison, 5.6 million persons lived in neighborhoods with poverty rates of 40% or more, about 3% of the US population. Thus, it is a mistake to assume that underclass areas are identical to or a subset of high-poverty areas – for example, the poorest of the poor neighborhoods. Nearly 4 in 10 of all underclass tracts in 1980 were not high-poverty areas, and 72% of these extreme poverty areas were not underclass tracts. Ricketts and Sawhill concluded that the two concepts, while highly correlated, are qualitatively distinct phenomena.

Using 1970 and 1980 Census Data, Ricketts and Mincy (1990) documented a dramatic growth in the underclass during the 1970s. They used 1980 means and standard deviations on the four indicators and applied these retrospectively to the 1970 census data. The number of underclass census tracts grew 331%, from 204% in 1970 to 880% in 1980. The population more than tripled, rising from 752 000 to 2.5 million (Ricketts and Mincy, 1990: p. 140). This rapid growth confirmed the general belief that social conditions of the inner cities, where almost all underclass tracts were located, were deteriorating rapidly during this period. Mincy and Wiener (1993) used the Ricketts–Sawhill definition to estimate the growth of the underclass population during the 1980s, by applying the 1980 thresholds to 1990 Census data. They report that 2.7 million people, 1.1% of the total US population, lived in such areas. These figures represent increases of less than 10% over the 1980 levels for both the number of tracts and their population (Mincy and Wiener, 1993: Table 1). Compared with the dramatic growth in the underclass during the 1970s, the population living in underclass areas increased by only 8% in the 1980s (Mincy and Wiener, 1993: Table 1), while the population living in concentrated poverty areas rose by more than 54% (Jargowsky, 1997: p. 38). Once again, the evidence suggests that the underclass phenomenon differs from concentration of poverty and must be considered a distinct dimension of the urban poverty problem.

The most recent analysis suggests that, by the Urban Institute measure at least, the underclass declined dramatically in the 1990s. Applying 1990 means and standard deviations to the 1990 and 2000 census tract data, Jargowsky and Yang (2006) found a substantial decline in the number of underclass census tracts (−32.5%) and the population living in them (−36.4%). The decrease was driven largely by an increase in high-school graduation rates and a decrease in the receipt of public assistance, the latter being driven by the 1996 welfare reform enacted under President Clinton that substantially reduced welfare receipt. These changes reduced the correlation between the four underclass measures, therefore reducing the probability that any one census tract would be one standard deviation above the mean on all four measures. Although the sensitivity of the underclass measure to correlations among the four measures is problematic, the drop in the underclass phenomenon is consistent with other measures of conditions in inner-city neighborhoods, such as declines in violent crime rates in most major cities during this period (Jargowsky and Sawhill, 2006).

Current Status of the Underclass

The concept of the underclass has largely fallen from use since its heyday among social scientists in the 1980s and 1990s. Despite the controversy over its freighted moral meanings, empirical imprecision, and association with discredited notions of cultural causes of poverty, the term retains a latent power for some. As the cause of alleviating inner-city poverty has declined in the United States, and politics have turned against the poor, yet a new set of conditions reflecting deeply rooted racial and class inequality has arisen, and the underclass idea appears to be making a mild return. The crisis of incarceration and the militarization of the US border have expanded the pool of the poor now legally confined, restricted, and excluded from economic and education opportunity. Under the structural conditions of legal regimes that confer second-class citizenship (rather than simply a function of capitalist exploitation), some – including former critics of Wilson's treatment of the underclass concept – have returned to the notion of a racialized subset of the poor permanently trapped in a subordinate class that threatens the well-being and status of coethnics and even the rest of society. For example, Massey and Pren (2012) argued that current US immigration policies are leading to the emergence of a new Latino underclass. Approximately half of all Mexicans in the United States as of 2012 are undocumented, and therefore they are cut off from mainstream employment opportunities, social services, and public higher education. "The burden of illegality," Massey and Pren wrote, "constitutes the single largest and most potent barrier to Hispanic socioeconomic mobility and integration in the United States" (2012: p. 15).

In the final analysis, the term 'underclass' is seldom used in the twenty-first century as an analytic concept. The contentious debates over the exact meaning and normative implications of the term diverted attention from the underlying phenomena of urban poverty, joblessness, and dependency. To the extent that the term is still used, it refers to groups who are cut off structurally from the pathways to social and economic mobility. At least two groups satisfy this condition – undocumented immigrants, who cannot access the mainstream labor market or many social services, and the ex-offender population, which likewise is cut off from employment opportunities and other vestiges of true citizenship, such as voting. Public policy will need to address these and other structural impediments to economic mobility, or the nation will be at risk of creating a permanent underclass of people with no hope of escaping from poverty.

Abstract

In this article we first review what is generally believed to be the case regarding the relationship between unemployment and mental health. Since we believe the treatment in the dominant literature of both 'unemployment' and 'mental health' to be critically problematic, we then subject each domain to brief critical examination. We close by suggesting ways in which we need to progressively move forward in theory and practice.

Classic Psychological Research on 'Unemployment' and 'Mental Health'

Researchers in the 1930s (e.g., Österreichischen Wirtschaftspsychologischen Forschungsstelle, 1933; Pilgrim Trust, 1938: see Fryer, 1986a; Jahoda, 1982 for a more detailed account) carried out unemployment research in the context of mass unemployment and hunger marches to determine whether mass unemployment would lead to revolution or apathy: the answer given was the latter. Researchers in the 1970s and 1980s were more concerned with the question of whether the association between 'unemployment' and 'indicators of poor mental health' was to be explained by processes through which those with poorer mental health were more likely to become and remain unemployed (individual drift) or processes through which healthy people who became unemployed became less mentally healthy (social causation). While still trying to explicate a causal relationship, research in the 1990s and 2000s has focused on the different effects of unemployment between individuals, e.g., Leana and Feldman (1995), and how identifying these 'moderators' can be used to fine tune intervention technologies, e.g., Paul and Moser (2009). The shift from a more social and political understanding of the problem of unemployment to a problem with the individual reflects a wider and increasing influence of neoliberalism in the Global North.

The accumulated research about the 'psychological costs' of 'unemployment' is now vast. Maynard and Feldman (2011), for example, reported that their search of relevant databases (PsycINFO, SocIndex, etc.) had revealed 31 839 peer-reviewed works with 'unemployment' in the abstracts published in the previous 50 years. However, large bodies of literature had assembled long before this, e.g., in 1938 Eisenberg and Lazarsfeld were able to review well over a 100 studies relating to 'the psychological effects of unemployment' (Eisenberg and Lazarsfeld, 1938) and even in 1909 Taylor was able to assemble a compendious 'Bibliography of Unemployment and the Unemployed' (Taylor, 1909).

A huge and diverse body of unemployment research has been carried out: in a wide variety of geographical settings; across a wide variety of historical periods; from a wide variety of diverse funding bases; at a variety of 'levels' (individual unemployed people, unemployed families, cohorts of school-leavers, whole redundant workforces, populations of states or whole countries, etc.); and has been characterized by researchers' use of a wide variety of methods and research designs (psychiatric assessment, qualitative interviewing, cross-sectional and longitudinal surveys using validated reliable measures, epidemiology, action research) (Fryer, 1986a but see Fryer, 2014). For many researchers, well-designed longitudinal studies in the 1980s using standardized measures and tracking large, carefully matched, samples of people in and out of employment-related transitions were the key studies. Some of the – for many – most persuasive longitudinal quantitative studies were done with young people using standardized measures, deemed reliable and valid, of anxiety, depression, positive and negative self-esteem, a variety of measures of affect and 'psychological well-being.' Typically, these studies measured the 'mental health' of large groups of young people in school and then followed them through labor market transitions, periodically measuring the 'mental health' of those who got jobs and those who did not, and comparing group mean scores cross-sectionally and longitudinally. Groups of unemployed youngsters have been repeatedly demonstrated to have poorer 'mental health' than their employed peers but statistically significant differences are seldom found between the scores of the same groups when at school (Warr, 1987). Many such studies have been done, but three longitudinal research programs have been particularly influential. The first was the 1980s research program based at the Social and Applied Psychology Unit in Sheffield, England – (see Warr, 1987 for an overview). The second program was based at The Flinders University of South Australia – (see Feather, 1992; Feather and O'Brien, 1986 for overviews). The third was based at the University of Adelaide – (see Winefield et al., 1993 for an overview). In brief, such studies provided powerful evidence within a mainstream frame of reference that unemployment causes, rather than merely results from, poor psychological health.

Statistically sophisticated meta-reviews have pooled data from a variety of studies (e.g., McKee-Ryan et al., 2005;

Paul and Moser, 2009) and there has been widespread agreement that 'unemployment' is not only associated with but 'causes' individual misery and mental health problems including anxiety, depression, negative self-esteem, dissatisfaction with life, social dislocation, community dysfunction, and population morbidity – (see Classen and Dunn, 2012; Jefferies et al., 2011; Keily and Butterworth, 2013; Kim et al., 2012). While caveats, criticisms, and controversies have been raised in relation to this huge body of research, they are mostly relatively minor and overwhelmingly raised *within* the frame of reference of such research, rather than of it. It is now difficult to contest, within the dominant modernist research frame of reference, the claim that 'unemployment' has a detrimental impact upon the 'psychological well-being' of 'unemployed people.'

The Scale of 'Unemployment'

In September 2013, unemployment in the UK as indicated by those claiming financial support stood at 1 401 800 (the 'claimant count'). However, according to the International Labour Organisation (ILO) way of counting them, 2 487 000 people in the UK were unemployed. Moreover, 1 447 000 people were *involuntarily part-time employed* being unable to find full-time employment and a further 8 961 000 people were deemed '*economically inactive*' – this included those who want to be employed but had stopped active job search because depressed or pessimistic about the chances of success (all the above figures accessed at http://www.cesi.org.uk/statistics/labour/september-2013 on 15 October 2013).

Unemployment in Europe, and in some European countries in particular, at the time of writing this article, is extremely high and getting worse. Even according to ILO figures, which understate the scale of unemployment, according to Eurostat, in April 2013 *19 375 000* men and women were unemployed in the 17 countries of the euro area, a rate of *12.2%*, and *26 588 000* men and women were unemployed in the Euro-27 countries (a rate of *13%*). Unemployment increased by 1 673 000 in the EU-27 and by 1 644 000 in the euro area since April 2012. Greece, Spain, and Portugal had unemployment rates of *27*, *26.8*, and *17.8%*, respectively. Youth unemployment tends to be proportionately higher than adult unemployment. The youth unemployment rate was close to 25% in the euro area. The ILO-calculated global unemployment was *197 000 000* in 2012, increasing to *202 000 000* in 2013 and *205 000 000* in 2014 (http://www.ilo.org/wcmsp5/groups/public/—dgreports/—dcomm/—publ/documents/publication/wcms_202326.pdf accessed 28.05.13.).

If one accepts that 'unemployment' causes 'mental health' problems and accepts that the scale of unemployment is colossal globally, unemployment is a public mental health catastrophe.

We do not doubt that 'unemployment' (but also under- and overemployment) as currently neoliberally constituted in Organisation for Economic Co-operation and Development (OECD) countries are intimately interconnected with individual, family, community, and societal misery, morbidity, mortality but we do regard the dominant ways in which this is documented, explained, and intervened into to be profoundly problematic. We elaborate on this next.

The Terms 'Unemployment' and 'Mental Health'

How unemployment is conceptualized, defined, and operationalized (translated into a measurement procedure) determines who and how many is/are included (and excluded) in official 'counts' of 'the unemployed,' productively constrains who are selected as participants in empirical unemployment research and has wider ideological implications, which are explored below: by 'ideological implications' we mean implications regarding the interests served by different systems of knowledge claims.

Unemployment used to be widely operationalized in 'developed' countries as a count of those who were 'claimants' of unemployment-specific financial support. Changes in eligibility for financial support could – and often did – reduce the number of claimants without reducing the number of unemployed people. Currently, most countries use the ILO criteria for positioning people as unemployed, and therefore, also to determine the number of unemployed people. These ILO criteria position people as unemployed if they have not undertaken paid employment in the survey reference week, have looked for a job within the previous 4 weeks and are available to start one within 2 weeks, irrespective of whether they are or not in receipt of unemployment-related benefits. People without employment who want paid work but cease to actively look for employment are referred to as the 'discouraged' and are not included in the 'unemployment' figures. The unemployment rate in the UK in September 2013 was 7.3% but the Economics Policy Institute estimated that if unemployed people who had ceased active job search were included that figure would jump to 9.5% (Shierholz, 2013). If decades of psychological research regarded by most unemployment researchers as having demonstrated beyond reasonable doubt that people who become 'unemployed' are disproportionately likely to be depressed, anxious, demoralized, low in self-esteem, socially isolated, etc., (Fryer, 2012; Wanberg, 2012) i.e., discouraged as a result of being unemployed are taken seriously, in countries which use the ILO operationalization of 'unemployment' becoming 'unemployed' can lead to no longer 'counting' as 'unemployed' and thus be effectively 'disappeared' socially, economically, and politically (Fryer, 2014).

Reviews of the field comparing studies drawing upon rather differently constituted unemployed 'samples' should also, therefore, be treated with caution. Reviewers often seem to assume that 'unemployed people' can be lumped together for research purposes whether 'unemployed' in the 1930s, 1980s, or 2010s, although the sampling and the socially constituted nature of 'unemployment' were quite different at different times in different places.

From our standpoint, unemployment is socially constituted in different ways over time and this constitution involves a complex set of dynamic interconnections between dominant discourses, government policies, bureaucratic processes and procedures, administrative technologies, psychological knowledges, forms of subjectification, etc. (see also Baxandall, 2002; Walters, 2000; McDonald and Marston, 2005). The way unemployment is socially constituted has important research, policy, subjective, and ideological implications. The problem is not so much that the ILO operationalization is not broad enough to cover diverse manifestations of unemployment but

rather that it constructs a very particular and ideologically problematic way of understanding 'unemployment.' It is essential not to naturalize the dominant constituted version of 'unemployment' or take it for granted as 'real' but rather to emphasize that it is socially manufactured, historically and culturally contingent, has a genealogy that can be traced and functions to serve some interests rather than others.

If unemployment is a complex social construction, which has changed over time in certain respects, then 'mental health' and psychiatric diagnostic practices are even more evidently, widely problematized, social constructions. So-called 'users of psychiatric services,' survivors of psychiatry, emancipatory disability researchers, antipsychiatry activists, and many others have critiqued the psychopathologization of diverse ways of being human and recently there has been a cacophony of criticism of DSM-5, the text which sets the criteria for 'mental disorder' diagnosis, and the ways of engaging and some would say constituting mental ill-health it implies (e.g., Timimi, 2013). Without denying the distress experienced, the authors of this article position what acritical mainstream scientists refer to as 'major forms of depression' as currently 'existing' only in the sense that they are currently repeatedly socially constituted as 'real' through deployment of dominant discourses, procedures, technologies, etc. Some mainstream authors criticize psychiatric diagnostic practices but position what they consider to be 'appropriately defined forms of major depression' as existing in a realist sense, in themselves but also via elevated risks of comorbidity (Prince et al., 2007) and of suicide (Classen and Dunn, 2012). The notion of cause and effect has long been under fire in relation to human actions and subjectivity. For all these reasons the claim that there is a causal relationship between the changing social constructions, unemployment, and 'mental health,' – or should in contemporary times – be a controversial one.

Explaining the Effects of 'Unemployment'

This brings us to the question of why the lives of so many unemployed people are plagued by misery, morbidity, and, according to some research, mortality. The most influential such explanation is that of Marie Jahoda (1982) who argued that although the intended function of employment was to earn a living, employment also had unintended functions (an imposed time structure, engagement in regular social contact, participation in a collective purpose, receipt of a social identity and required regular activity) the deprivation of which – by unemployment – was responsible for the psychological consequences of unemployment. What is psychologically bad about unemployment, according to this account, is deprivation of benevolent psychologically structuring features of employment. However, many privileged, secure, wealthy, and privileged nonemployed people in the hugely unequal societies of the OECD manage 'psychologically,' relatively at least, very well indeed without having the 'psychological benefits' of employment imposed upon them and of course there is another literature documenting that the employment of many people is psychologically and physically destructive, so this cannot be the whole story. We have long ago offered a wider critique of Jahoda's account and offered an alternative meta-approach in terms of the restriction of agency by unemployment by poverty and powerlessness, especially over the future (e.g., Fryer, 1986b), but these days we are exploring the ways people, when unemployed, are subjectively and materially (re)constituted so that they come to embody, and perform themselves to reproduce a socially and historically produced and psychologically destructive, unemployed identity.

Some variation from person to person in the experience of unemployment is reported, widely explained by researchers in terms of the moderation of the relationship between unemployment and mental health by variables: operationalizing age, length of unemployment, employment commitment, poverty, gender, etc. Strikingly, *however*, the broad psychological impact of unemployment is, according to researchers, with minor caveats, not only psychologically destructive but also, phenomenologically speaking, extraordinarily consistent. *The consistency* in the nature and detail of that destruction across time space and culture *is found* despite huge variation in the nature of employment, the nature of work, the labor market, the nature and degree of support for people, distribution of wealth, dominant social values, etc., from the 1930s to the twenty-first century and from country to country. We regard the consistency of the results of subjectification of unemployed people across time and space as telling us more about the functions served by unemployment, and in particular the unemployed subjectivity, which is repeatedly reconstituted, for the economic and political neoliberal status quo than it does about replication of effects of unemployment (Fryer, 2014; see also McDonald and Marston, 2005; Schram, 2000). Our view is that a network of interconnected constructed and maintained social elements, including discourses of unemployment and mental health (and implicated psy-complex constructions like psychological well-being and misery) whose primary function is to control inflation, reduce wage costs, discipline, etc., also simultaneously constructs and 'makes real' a category of 'the unemployed' necessary to make the neoliberal labor market work in the interests of employers and shareholders, i.e., capital. *The* category *of 'the unemployed'* is composed of different people on the basis of varying criteria at different times and different places and is only meaningful, i.e., only exists, by reference to that network. The subjectivity of 'the unemployed' *is constituted* in such ways as to (re)produce the compliant human means of production required by the employers, shareholders, and government within the contemporary version of the neoliberal labor market. *The* subjectivity of unemployed people *is reconstituted* as phenomenologically aversive, socially stigmatized (for example, see Gibson, 2009), and psychopathological.

Future Directions of Theory and Research

Foucault (1979/2008) lectured specifically about neoliberalism in *The Birth of Biopolitics*. Rejecting the view that neoliberalism is laissez faire in all respects Foucault stated: "neoliberal governmental intervention is no less dense, frequent, active, and continuous than in any other system. But what is important is to see what the point of application of these governmental interventions is now… Government must not intervene on effects of the market. Nor must neo-liberalism, or neo-liberal government, correct the

destructive effects of the market on society… Government must not form a counterpoint or a screen, as it were, between society and economic processes. It has to intervene on society as such, in its fabric and depth" (p. 145).

We can see this very clearly in the logic of 'workfare,' which demands that unemployed persons not only prove they are actively seeking work but are also actively working on themselves through "self-examination, counselling, self-help groups…" (Dean, 1995: p. 575). Psychologically oriented active-labor-market-promoting intervention research projects have included recommendations that unemployed people receive cognitive behavior therapy (Proudfoot et al., 1997; see also Wanberg et al., 2011; Karren and Sherman, 2012) or other employment-specific programs like the JOBS Project (http://www.isr.umich.edu/src/seh/mprc/jobsupdt.html), which "involves the design and evaluation of a preventive intervention aimed at providing job-seeking skills to promote reemployment and to combat feelings of anxiety, helplessness, and depression among the unemployed." The JOBS project resonates, of course, with the 'Improving Access to Psychological Therapies Programme' (http://www.iapt.nhs.uk/). While these may well reduce unemployment in the target intervention groups, in a situation where the number of unemployed people vastly outnumbers the number of employment vacancies, they cannot of course do anything more than reorder the queue of unemployed people looking for employment (Fryer, 1999). At a time (September 2013), 2 487 000 people were unemployed in the UK but there were only 531 000 vacancies for paid work (http://www.cesi.org.uk/statistics/labour/september-2013 accessed on 15.10.13). Such approaches make no sense at a public mental health level since they result in the same number of people being constituted as unemployed with all that implies. These active labor market programs shift the responsibility onto the individual and simultaneously blame the individual for failing to reenter the work force and for their own suffering. Psychology, in providing the psy-complex resources for such (re)subjectification (Rose, 1999), contributes to the normalization of this shift of responsibility onto the individual, which then prohibits or limits possible self-intelligibilities; ones which may lie outside a neoliberal subjectivity (Brady, 2011) including potentialities for resistance.

The reconstitution of subjectivity includes the constitution of subjectivities positioned as pathological in terms of dominant ways of thinking, speaking, and acting in relation to 'mental illness.' Getting to grips with this constitution is a matter of getting to grips with "how statements about mental illness are given the status of being 'true'; how collections of interconnected statements about mental illness are given the status of being 'knowledge'; how forms of surveillance are given the status of 'care'; how forms of assault are given the status of 'treatment'; how the speech and action of some is positioned as 'expertise' with the consequent authority to decide whether others are to be compulsorily detained, have 'treatment' forced upon them etc." (See Stambe et al., 2012: p. 9).

In this article, we have explored a range of positions taken up by unemployment researchers regarding whether the apparent relationship between 'unemployment' and 'mental health' is to do with 'natural' and inevitable psychobiological consequences of depriving an unemployed person of employment-related, psychologically necessary, structures, to do with the frustration of the agentic potential of the individual unemployed person or to do with psychological states that are objectively identifiable as healthy or pathological. These positions have been subjected to a critical examination and we have mapped out our own position, that the apparent relationship between 'unemployment and mental health' is a set of connected manifestations of material, social, and subjective violence, which function to make the neoliberal labor market work in the interests of employers and shareholders. In the view of the current authors, future research on 'unemployment' needs to move away from the psy-complex's individual-blaming manifestations, which work for an oppressive neoliberal status quo, develop progressive emancipatory counterknowledges, and create discursive spaces in which it is possible to think about ourselves without colluding with neoliberal subjection.

Unemployment: Structural

Assar Lindbeck, Stockholm University, Stockholm, Sweden

Abstract

Structural unemployment differs from cyclical unemployment by not disappearing in cyclical booms. In economic theory, structural unemployment is usually analyzed in terms of the concept of equilibrium unemployment (the 'natural unemployment rate' in Friedman's terminology). Two elaborate concepts of equilibrium unemployment – the nonaccelerating inflation rate of unemployment and the unemployment rate that induces firms and workers to accept the same real wage (the PS–WS model) are used as analytical framework for the article. These models are also related to search models for the labor market, in which unemployment equilibrium is defined as a situation where the number of individuals finding jobs equals the number of individuals who are separated from jobs. But it is argued in this article that it is reasonable to widen the concept of structural unemployment to also include unemployment persistence, that is, a tendency for unemployment to continue to be high for quite a while also after temporary unemployment-creating shocks. This article pinpoints various factors that influence the level of structural unemployment, which differs in time and place. It ends with a discussion of how structural unemployment is influenced by policy actions.

Definitions

It is an old tradition in labor economics to distinguish between structural, frictional, and cyclical unemployment. Structural unemployment is then envisioned as a result of the institutional set up of the economy, including private and government organizations, types of market arrangements, demography, laws, and regulations. In the literature, the importance of these institutional features for structural unemployment is tied particularly to their implications for demand for and supply of labor, price and wage formation, and the efficacy of search and matching processes in the labor market. Frictional unemployment may be regarded as a subset of structural unemployment, mainly reflecting temporary unemployment spells as the result of job search and matching difficulties in the connection with quits, new entries to the labor market, and job separation because of the employers' dissatisfaction with individual workers.

Cyclical unemployment differs from structural and frictional unemployment by basically being tied to short-term economic fluctuations. An empirical illustration of the importance of structural unemployment as compared to cyclical is that variations in actually measured unemployment rates have turned out to be much larger between cycles than within cycles, presumably reflecting differences in structural unemployment (Layard et al., 1991). For example, the average unemployment rate over the business cycle in Western Europe has moved from about 3% in the mid-1960s to 6% in the mid-1970s and to 10% from the mid-1980s to the late 1990s. But as pointed out below, various unemployment-persistence mechanisms blur the distinction between cyclical and structural unemployment.

In economic theory, structural and cyclical unemployment usually are regarded as disequilibrium phenomena in the sense that they reflect excess labor supply at existing wages and hence that the labor market does not clear. Then, individual employers informally ration jobs. Nevertheless, technically (analytically) structural unemployment often is analyzed in terms of the concept of *equilibrium unemployment*. This means that the aggregate-unemployment level is in a 'state of rest': existing excess labor supply is assumed to last as long as certain characteristics (parameters) of the economy are unchanged. If this equilibrium is dynamically stable, unemployment equilibrium may also be described as an unemployment level toward which the economy moves as long as new disturbances do not emerge. (The term 'equilibrium' is used in several different ways in economics. It refers sometimes to the equality between demand and supply in a market, i.e., to traditional 'market- clearing,' in other cases to a state that tends to continue over time regardless of whether the market clears or not. The concept of 'equilibrium unemployment' is an example of the latter.)

It is useful to distinguish between two main analytical approaches to equilibrium unemployment: *stock approaches* and *flow approaches*. Stock approaches focus on the difference, at a given point in time, between the workforce desired by firms (aggregate *stock demand* for labor) and the number of workers willing to work (aggregate *stock supply* of labor). Flow approaches deal with the difference between the flows in and out of the unemployment pool during a certain period. Flow-demand for labor is represented then by the supply of 'job slots,' and flow-supply by offers of workers to fill such slots. These two approaches are related because stock demand and stock supply may also be derived in flow approaches. Let us start with stock approaches.

Stock Equilibrium

Milton Friedman's celebrated 'natural unemployment rate' is a stock-equilibrium concept of structural unemployment: 'the level that would be ground out by the Walrasian system of general equilibrium equations, provided there is imbedded in them the actual structural characteristics of the labor and commodity markets, including market imperfections, stochastic variability in demand and supplies, the costs of gathering information about job vacancies and labor availabilities, the

costs of mobility and so on' (Friedman, 1968). Apparently, this concept of equilibrium unemployment covers structural and frictional unemployment as described earlier.

The nonaccelerating inflation rate of unemployment (NAIRU) is close to Friedman's natural rate, though it emphasizes (more than Friedman does) the nonclearing character of the labor market. The NAIRU is defined explicitly as the unemployment rate at which inflation is constant. It is derived from an expectations-augmented Phillips curve, i.e., a function that assumes that the price-inflation rate is a decreasing function of the unemployment rate and an increasing function of the expected rate of future inflation (Phelps, 1967). In the simplest possible terms (with linear relations):

$$\pi = -au + b + c\pi^{e} \qquad [1]$$

where π is actual inflation, u is the unemployment rate, and π^{e} is expected inflation. For given values of the (positive) parameters a, b, and c, the equation may be depicted as a set of downward sloping short-term Phillips curves (SR_i), one curve for each set and for each value of π^{e} (see **Figure 1**).

In the context of this model, usually (and realistically) it is assumed that economic agents ask for full compensation for expected inflation in the *long run*; thus $c = 1$ in that time perspectives. It is usually also assumed that economic agents do not make *systematic* expectational errors in the long run; thus $\pi = \pi^{e}$. The only unemployment rate consistent with these two assumptions is, from eqn [1], $u^* = b/a$, where * denotes the equilibrium unemployment rate. It is often also assumed that inflation in this situation is constant over time (and not just that actual and expected inflation coincide), because agents have no reason to revise their price and wage setting behavior when inflation is exactly what they had expected when they formed their decisions. u^* is then the NAIRU (the unemployment rate at which inflation is constant), geometrically represented as a vertical long-run Phillips curve, LR in **Figure 1**. Inflation increases to the left of that level and falls to the right. Because inflation in this framework in the long run is independent of unemployment, there is no long-run trade-off between these variables. But it has been argued by Lucas (1972) that there is not even a *systematic* short-term trade-off if economic agents have 'rational expectations' (thus, if they never make systematic expectational errors), and if various agents are free to revise their prices and wages in response to changes in expectations. Such a trade-off will then only arise due to random (nonsystematic) expectational errors, e.g., due to random shocks or randomized government policy.

An alternative exposition of stock-equilibrium in the labor market, and hence structural unemployment, gained ground in the 1980s and 1990s; it emphasizes the requirement of consistency of price- and wage-setting behavior (Shapiro and Stiglitz, 1984; Layard and Nickell, 1986). **Figure 2** gives a simple diagrammatic illustration, with aggregate employment (N) on the horizontal axis and the aggregate real-wage level (w) on the vertical. The LS curve is the traditional aggregate labor supply curve, i.e., the sum of labor supplied by households. The PS curve is the price-setting curve of firms: for alternative unemployment levels and given nominal wages, the curve defines the price level desired by profit-maximizing firms that operate in imperfectly competitive product markets. Or the PS curve can be described as a labor-demand relation, because it also expresses the combination of employment and real wages desired by profit-maximizing firms. Unemployment is then the horizontal difference between the PS and LS curves.

The WS curve defines wage-setting behavior. It depicts the influence of the (un)employment situation on the real-wage rate that the wage-setting process generates. The intuition is that firms feel compelled to offer higher real wages and that workers and unions demand higher real wages when the labor market is tight (low unemployment) than when it is slack. So by contrast to models with perfectly competitive labor markets, a distinction is made between labor supply (by households) and wage setting (by firms, unions, or more realistically a bargaining process).

The equilibrium real-wage rate is now w_0, equilibrium employment N_0 and equilibrium unemployment U_0, the latter being the only unemployment level at which there are no incentives for agents to change prices relative wages and vice versa (corresponding to the equilibrium unemployment rate

Figure 1 Phillips curves and the NAIRU.

Figure 2 The PS–WS model of equilibrium unemployment.

u^* in Figure 1). This model will be called the PS–WS model of equilibrium (structural) unemployment.

As an illustration, suppose that the real-wage rate in Figure 2 is initially w_0 but that aggregate employment happens to be above N_0, e.g., as a result of positive demand shocks to which nominal magnitudes have not yet adjusted. Firms and workers are then dissatisfied with the existing real wage w_0 Workers and their unions try to raise nominal wages (at existing nominal prices), as can be read off from the WS curve, and firms try to raise prices (at existing nominal wages), as can be read off from the PS curve. The result is a wage-price spiral, as described by the expectation-augmented Phillips-curves model. Firms also start cutting their work force because their desired level is lower than the actual one. Aggregate employment continues to fall until it reaches the unique equilibrium level N_0. The same reasoning, *mutatis mutandi*, holds if aggregate employment is initially lower than the equilibrium level.

Flow Equilibrium

Flow approaches to structural unemployment instead emphasize the flow of workers in and out of unemployment (Phelps, 1970; Hall, 1979; Diamond, 1982). These approaches explicitly grant the heterogeneity of jobs and workers, which means that agents in the labor market must devote time and costs to search to match up idiosyncratic preferences, skills, and skill requirements. In the process, unemployment and vacancies coexist because the latter are not eliminated immediately by the hiring of workers in connection with decentralized negotiations of wages between firms and work applicants.

For simplicity, let us regard the size of the labor force (L) as constant. Further, let s denote the job separation rate, i.e., the fraction of employed workers (N) who lose their jobs in each time period. Let f denote the rate of job finding, i.e., the fraction of unemployed workers (U) who find a job in each time period. We assume that both fractions are constant. The equilibrium unemployment rate (u^0) is then defined as a situation when the number of individuals finding jobs equals the number of individuals who are separated from jobs; hence $fU = sN$. Noting that $N = L - U$, i.e., that the number of unemployed workers equals the labor force minus the number of employed, we get $fU = s(L - U)$ Rearranging terms and dividing both sides by L, we obtain the equilibrium, or structural, unemployment rate $u^0 = U/L = s/(s^{-1} + f)$. As expected, the higher the rate of job separation (s), the higher the equilibrium unemployment rate. And the higher the rate of job finding (f) – due to greater intensity and efficiency of job search and hence better job matching – the lower the equilibrium–unemployment rate.

Though the model basically is designed to highlight frictional unemployment, as described earlier, unemployment in the connection with job search and matching may also be due to continuing changes in the composition of demand and supply of different types of workers. This means that flow models of search and job matching also cover elements of what usually is regarded as structural unemployment, which illustrates the previous assertion that frictional unemployment may be regarded as a subset of structural unemployment.

It is natural and feasible to integrate flow and stock approaches to (un)employment determination. For instance, the efficacy of search and matching processes influences the positions of the PS and WS curves in Figure 2 (and the positions of the Phillips curves in Figure 1). The longer it takes firms to find the right workers for their vacancies, and the longer it takes work applicants to acquire suitable job offers, the more costly it is to hire workers, and the lower will be the labor-demand curve – the PS curve in Figure 2. A poorly functioning search and matching process will force recruiting firms to offer higher wages than otherwise; the result is also a higher WS curve. In this way, flow models are related to previously discussed stock models. Search and matching processes may also be seen as part of the short-term *dynamics* by which stock equilibrium is reached, with positive gross flows in and out of unemployment, netting to zero when there is flow and stock equilibrium.

Microeconomic Foundations

All these macroeconomic models of structural unemployment assume that unemployed workers are not able or willing to get jobs by underbidding the prevailing wages of incumbent workers. The most obvious microeconomic explanation of the absence of wage underbidding is perhaps *minimum wage laws*. But there seems to be rather general agreement among labor market economists that minimum wages have not been high enough in developed countries to explain much of aggregate structural unemployment in that part of the world. But in some countries, minimum wage laws are binding for specific types of workers, such as inexperienced, unskilled, and physically or mentally handicapped people. (In the special case when a firm has a monopsonistic position in a local labor market minimum wages may, up to a certain wage level, increase rather than reduce employment. In this case, the minimum wage simply prevents the firm from keeping down wage costs by holding back its demand for workers.)

There may also be informal *social norms* against the underbidding of the wages of incumbent workers. In other words, wage underbidding may not be socially acceptable behavior among workers, and the acceptance of such offers may not be socially acceptable behavior among firms. Legislation may support such norms.

But more elaborate microeconomic foundations of structural unemployment have been developed since the 1980s. In the *union monopoly model*, unions are assumed to strive for a trade-off between real wages and unemployment. Often, this trade-off is derived formally from a model where unions maximize the expected utility of union members – including those who are employed and those who wind up unemployed due to the union's wage policy. So labor unions are assumed conscientiously to choose a real-wage rate that generates some structural unemployment.

In *union-bargaining models*, the real wage is instead set in a bilateral bargaining process between a union and a firm or an association of firms. Such models qualitatively yield the same result as the union-monopoly model, though the real wage will normally be lower and hence the employment level higher, because the firm is assumed to strive for a lower real wage rate than the union. But neither type of union model answers the questions why there is no underbidding of existing wages by

nonorganized workers and why unemployed union members do not leave the union.

There are also theoretical reasons and empirical evidence why the organization of bargaining, such as the degree of coordination and centralization of bargaining, would influence the outcome of the bargaining process and hence also the unemployment level. The most generally accepted hypothesis is probably that both highly centralized and highly decentralized bargaining are more conducive to employment than wage bargaining on levels in between, such as industry-level bargaining (Calmfors and Driffill, 1988).

The *insider–outsider* theory of unemployment emphasizes the asymmetric market powers of incumbent workers, *insiders*, and disenfranchised workers without jobs in the formal labor market, *outsiders* (Lindbeck and Snower, 1988). Because hiring and firing costs protect incumbent workers, they can push up their wages above the reservation wage of outsiders without losing their jobs. Another way for insiders to prevent wage underbidding is by refusing to cooperate with underbidding outsiders in the production process and by threatening to harass them if underbidding workers are actually hired. With the help of such noncooperation and harassment threats, insiders (possibly with the support of unions) may also be able to create and sustain social norms in their own interest against wage underbidding.

In *efficiency wage* models, by contrast, the microeconomic foundations of structural unemployment are based on the incentive structure of firms (Yellen, 1984). Firms, which are assumed to have all market powers in wage formation, set wages high enough to get a good selection of work applicants and to discourage workers from shirking and quitting. More specifically, firms set wages to balance the cost of higher wages against the productivity increase of having a more efficient work force. Only by accident would the wage level that is optimal for firms clear the labor market.

All these microeconomic theories are rather silent about the employment situation in *informal* labor markets, where minimum wages are not always respected, unions may not exist, collective bargaining agreements are not binding, efficiency wages are not important, and labor turnover costs are very low and hence insider–outsider mechanisms not important. Extreme examples are sellers of flowers or newspapers on street corners, shoeshine boys, and workers in the underground economy. One conceivable explanation why some workers who are excluded from the *formal* labor market remain unemployed rather than choose to work in informal labor markets may be an unwillingness to take jobs that are regarded as highly insecure and demeaning. Generous unemployment benefits help them to make this choice. It is significant that informal labor markets are particularly important in countries without unemployment insurance.

In the popular discussion of structural unemployment, it is often believed that labor-saving technological progress and related increases in labor productivity will necessarily result in higher unemployment. Workers are asserted to become redundant because machines replace workers – a vision of *technological unemployment* as a special variation on structural unemployment. A usual conclusion is that some kind of work sharing is necessary to avoid ever-increasing unemployment. An obvious flaw of this argument is that a gradual rise in productivity will normally be accompanied by higher real wages and profits in the long run, and hence of real income. In this sense, productivity growth creates the foundation for higher demand for output, though deficiencies in aggregate demand may occasionally occur and contribute to recessions. In fact, no long-term trend of the unemployment rate can be detected during the twentieth century.

So work sharing – in the form of a lower general pension age, more generous rules for early retirement, or fewer working hours – is not necessary to prevent gradually rising labor productivity from resulting in rising unemployment. Indeed, the literature in the field clarifies that work sharing is not even likely to contribute to reduced unemployment except in the very short run; one reason is that a reduction of the labor force tends to push up wages. But there is nevertheless a potential problem with continuing productivity growth. Some national economies may fail to adjust to changes in the *composition* of the demand for labor in the connection with uneven rates of productivity growth among sectors and types of workers (sector shifts or skill shifts in the labor market). This is a respectable explanation as to why unemployment rates among low-skilled workers have increased so much (in percentage points) in Western Europe, where relative wages are quite rigid.

Unemployment Persistence

One serious limitation of the concept of unemployment equilibrium as an expression of structural unemployment is that this concept is difficult to distinguish empirically from unemployment persistence, i.e., inertia of unemployment after temporary shocks that have shifted the unemployment rate. Estimated equilibrium rates of unemployment tend to shadow the actual rate, which is an indication of unemployment persistence. Important examples of unemployment persistence are the persistently high unemployment rates after the deflationary policy pursued in several developed countries in the early 1920s and early 1930s; after the oil-price hikes in mid- and late 1970s; and after the restrictive monetary (and in some cases also fiscal) policy in the late 1980s and early 1990s. These experiences raise the suspicion that attempted statistical measurements of equilibrium unemployment also reflect the consequences of various persistence mechanisms. It is hard to find good reasons why the equilibrium unemployment rate in Western Europe should have increased as dramatically as the actual unemployment rate in the 1980s and 1990s.

There are also reasonable microeconomic explanations of unemployment persistence. While some explanations emphasize the behavior of outsiders, others point instead to the behavior of insiders. Examples of persistence mechanisms of the former type are the loss of skill among individuals who have been unemployed for a long time; endogenous changes in preferences in favor of leisure or household work; and the breakdown of social norms in favor of work and hence the emergence of unemployment cultures. We would expect reduced job search in all these cases. Long spells of unemployment may also function as a negative signal to prospective employers about the quality of individual workers. An example of a persistence mechanism that operates via the behavior of insiders is that they (possibly supported by unions) may exploit

subsequent business upswings to push up their wages, hence discouraging firms from expanding their workforce. All this suggests that unemployment persistence is an important factor behind what is usually regarded as structural unemployment. A basic conclusion is that endogenous changes of private behavior after a temporary unemployment-creating shock make the concept of *equilibrium unemployment* too narrow as a description of structural unemployment. For instance, it is realistic to regard prolonged high unemployment in Western Europe after the mid-1970s as the combined result of macroeconomic shocks and institutional rigidities that contribute to unemployment persistence. Hence, cyclical unemployment is asserted to have developed into structural unemployment. The result is strong 'history dependence' of the unemployment rate. So it is reasonable to widen the concept of structural unemployment to also include unemployment persistence.

Policies that Influence Structural Unemployment

Leaving the issue of legislated work sharing aside, what are the influences of government policy on structural unemployment? In the schematic PS–WS model presented earlier, the positions of the PS, WS, and LS curves reflect this influence. The discussion below is confined to taxes, transfer programs, regulations of job-protection, union powers, education/training, and other types of active labor market policy.

Taxes on labor insert a wedge between the labor costs paid by firms, the product wage $(1 + t_w)w$, and the return to workers, the consumption wage, $(1 - t_i)w$. t_w and t_i then denote the wage tax (payroll tax), and the income tax. *The tax wedge*, expressed as the ratio between the product wage and the consumption wedge, is then

$$(1 + t_w)/(1 - t_i) \qquad [2]$$

A consumption tax would enter the tax wedge in the same way as the wage tax. For example, in terms of **Figure 2**, an increase in t_w shifts the labor-demand relation (the PS curve) down, e.g., to PS: at every real-wage rate (w) the demand for labor will be lower than before because the firm must now pay $(1 + t_w)w$ for its labor. As long as the WS curve is unchanged, the equilibrium position shifts from point a to point b in the figure, and the equilibrium employment level (N) and the real-wage rate (w) fall. These effects are relevant in the short run. The long-run effects are less obvious, and they depend on the extent to which wage setting adjusts to the tax wedge, which in turn depends on what happens to alternative incomes of workers, such as unemployment benefits and the return on household work. But for low-skilled workers, wages are often tightly regulated, which means that the wage costs for firms are likely to rise and labor demand will fall for this specific group of workers.

The results of empirical studies on these matters are somewhat ambiguous. But on balance, it seems that aggregate employment is negatively affected by wider tax wedges not only in a short- and medium-term perspective but also in the long run (Nickell and Layard, 1999).

More generous *unemployment benefits* enable workers to be more selective about offered jobs and hence search for longer time periods – as highlighted by the earlier discussed search approach. Frictional unemployment (or *wait unemployment*) will then increase. Because the income loss in connection with unemployment becomes smaller, firms must offer higher wages to prevent shirking and to keep down quits, as highlighted by efficiency wage models. Moreover, workers and unions become less hesitant to ask for high wages, as emphasized by union and insider–outsider models. This tendency is accentuated by the fact that unemployment benefits are, as a rule, financed by taxes rather than by insurance fees directly tied to specific workers. In terms of **Figure 2**, the net effect of all this is that the PS curve is shifted down and the WS curve is shifted up, with rising equilibrium unemployment as a result. Unemployment persistence would also be predicted to increase.

Casual observation and systematic empirical studies, including cross-country regressions, suggest that generous unemployment benefits that may be kept for long periods (in some cases for several years or indefinitely), in fact, have effects of this type (Layard et al., 1991). Other evidence is that the exit rate for individuals from unemployment increases substantially in the US as soon as the benefit period expires after 26 weeks (Katz and Meyer, 1990).

Job-security legislation is often singled out as another factor that tends to raise structural unemployment. Basically, such legislation raises the costs of hiring and of firing workers, the former because firms must consider the possibility of future firing costs when hiring workers. Firms will be less anxious to fire workers in recessions but also less interested in hiring workers in business upswings. A predicted effect is that employment tends to be stabilized at the actually existing level whatever this happens to be. In other words, (un)employment persistence would be expected to increase.

Since such legislation increases the market powers of insiders, this helps them to push up their wages. The predicted effect is an increase in the average unemployment rate over the cycle. Moreover, the market power of insiders and unions depends also on other legislation. Important examples are rules that extend the coverage of bargaining agreements to nonunion firms and give large freedom for unions to use conflict weapons, such as the rights to sympathy strikes, secondary actions and blockades, and the right to take out small 'key groups' in conflicts.

Most government policies discussed earlier tend to raise structural unemployment (including unemployment persistence). Of course, the other side of the coin is that a reversal of these policies is likely to reduce structural unemployment. But there are also well known examples of government policies directly aiming to lower structural unemployment. Competition policy, which accentuates competition in product markets, induces firms to increase production and employment at given real wages; in terms of **Figure 2**, the PS curve shifts to the right. Increased competition in product markets also makes product demand more sensitive to changes in wage costs. This is likely to restrain the wage demands by insiders; the WS curve shifts down. The net effect would be lower equilibrium unemployment.

Active labor market policy is designed to keep workers out of open unemployment in the short term and to subsequently help them to get jobs. In particular, labor-exchange systems and retraining may improve matching between work applicants and vacancies. In terms of **Figure 2**, the PS curve shifts up and the WS curve down with falling structural unemployment as a result. Moreover, subsidized education and training that

raises labor productivity for (previously) low-skilled workers are likely to raise demand for them and reduce the upward wage pressure for skilled workers. This tends to generate similar shifts in the PS and WS curves as in the case of improved labor market exchanges. Unemployment persistence would also be expected to recede.

On balance, empirical studies suggest that labor-market exchange and properly conduced training programs, in fact, are useful for reducing structural unemployment (Layard et al., 1991); in the short term, also public works programs have such effects. But it is natural that the marginal return falls, possibly to zero, when the programs reach a large size (such as several percent of the labor force), and in particular when the programs are used largely to keep down statistically recorded figures on open unemployment.

Unintended Consequences: History of the Concept

Abstract

Unintended consequences might be linked to three problems in social sciences: purposive social action, human action (but not human design), and purposive social intervention. The treatments of these evolved rather autonomously within sociology, economics, and public policy analysis, respectively. Sociology established an interest in the unintended as deviation from rational-action accounts of social behavior. Economics investigated the spontaneous social order and the processes of aggregation leading to unintended configurations. Public policy analysis pointed to paradoxes and perverse effects of initiated institutional change. The proliferating analyses of unintended consequences as side effects, of perverse effects, and of paradoxes of modernization projects recently presented the empirical opportunity for the three perspectives to be compared and to further develop their conceptual backgrounds.

The problem of unintended consequences has claimed a central tenet in both sociology and economics. As a matter of fact, it is asserted, over and over again, to be the main concern of social sciences. The fascination with the unintended stems from the fact that processes occurring in a linear fashion do not constitute a problem and challenge for social sciences while unexpected occurrences do (see Popper, [1945]2013: 307; Portes, 2000). The term 'unintended consequences' is used less in relation to overtly stated intentions, but more so to depict outcomes of social action which contravene to the interests of the actors (Popper, 1957: 157). In addition, it pertains to indirect effects and the change of goals during the implementation of certain intentions that are depicted in a paradoxical manner.

Unintended Consequences of Purposive Social Action versus Unintended Consequences of Human Action, But Not of Human Design

The treatment of unintended consequences in sociology and economics was inevitably influenced by the insights of political thought, moral philosophy, and history (Vernon, 1979). This common heritage notwithstanding, an essential difference in approach is apparent. Sociology, from a functionalist background and guided by Robert K. Merton's (1936) analysis of unanticipated consequences of purposive social action, dealt predominantly with the reasons why actions produce unexpected outcomes and the subjective processes conditioning their anticipation. Further, it gave priority to unintended consequences that pertain to negative or undesirable effects. While, economics, building upon Adam Smith's ([1759]1976, [1776]1975), Adam Ferguson's ([1767]1966), and David Hume's (see discussion in Barry, 1982; Hamowy, 1987, 2008) ideas of the invisible hand and spontaneously created social institutions, favored a treatment of unintended that focused on structured patterns resulting from separate actions which did not intend the overall resulting order.

In sociological fashion, unintended consequences were predominantly traced to social action. They were "a particular effect of purposive action which is different from what was wanted at the moment of carrying out the act, and the want of which was a reason for carrying it out" (Baert, 1991: 2). On the other hand, in economic thought, they were defined in relation to social interaction as "establishments, which are indeed the result of human action, but not the execution of any human design" (Ferguson, [1767]1966).

Albert O. Hirschman (1991) identified the three unintended narratives within the 'rhetoric of reaction' against programs of social intervention – i.e., the perversity thesis, the futility thesis, and the jeopardy thesis. Following this logic, the two outlined treatments in the sociology and economics of the unintended, though not reactionary per se, might be termed as the unanticipated-perverse effect perspective (UPE) and the invisible hand-spontaneous order interpretation (ISO).

Intellectual Backgrounds

Within sociology, UPE states that because of limitations of foresight of consequences of social action, the actions of individuals have consequences that are unintended and sometimes even contrary to what was pursued and anticipated. In terms of reactionary rhetoric, Hirschman (1991) traced the formulation of the perversity thesis to Edmund Burke's prediction, and Joseph de Maistre's theological view of the French Revolution, as well as to treatments of the unexpected and invisible hand in Giambattista Vico, Bernard Mandeville, and the Scottish Enlightenment.

Taken in its broadest, UPE covers two out of five of the alternative action sequences to the linear purposive action that were identified by Alejandro Portes (2000, 2010). These two notions are the shift of goals during a given activity (e.g., Max Weber's thesis on the effect of rational ascetism on economic behavior, Robert Michels' iron law of oligarchy) and the unexpected outcome (e.g., Georg Simmel's analysis of cumulative outcomes, Merton's unanticipated consequences of social action). The mid-course shift, after initially being termed as 'the essential paradox of social action' (Merton, 1936), suffered a somehow arrested development on the unintended agenda until it was rediscovered, a few decades later, by public policy analysts (Sieber, 1981; Hirschman, 1977) and sociologists (see Schneider, 1975; Cherkaoui, 2007 – see also discussion in Lal, 1998; Symonds and Pudsey, 2008). In contrast, the unexpected outcome exercised a prevailing

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03176-7

influence in modern sociology from the very beginning. Portes (2000: 10) defined it as involving "end-states that are qualitatively distinct, and sometimes the opposite of, those originally intended."

The pervasive influence of Simmel notwithstanding, it is Merton's (1936) treatment in the seminal article *The Unanticipated Consequences of Purposive Social Action*, which is broadly considered to be the first initiative to establish sociology as the 'analysis of the unexpected' (Portes, 2000; Mica et al., 2011). In this article, Merton (1936: 904) addressed 'social prediction, control, and planning' and differentiated five 'types of social action' by indicating limitations of 'correct anticipation of consequences of action'. As indicated by Portes (2010: 19), "the essay opened the door to a number of modern concepts, all highlighting the paradoxical nature of social life," Merton himself is being one of the main contributors to this list.

The notions advanced by Merton were quite distinct in terms of structural range and type of interest in the relationship between the consequences and the initial intention. Despite this broad compass, they focused sociology on the subjective processes determining the foresight of consequences and, contrary to Merton's intention, reinterpreted the unintended consequences as unexpected and undesirable. As pointed out by Patrick Baert (1991), this path dependence was linked to the broader functionalist framework hosting the unintended debate, and to the fact that sociologists drew their empirical cases from policy-relevant areas, in which the initial intentions became frustrated. On the other hand, the sense of superiority and fascination with paradoxical and counterintuitive outcomes enjoyed by sociologists, who were skeptical of systemic theories grounded on purposive social action, cannot escape notice.

In comparison to sociology, economics, at least in the ISO perspective, seems to have escaped such an 'anti-unintended bias'. ISO depicted social institutions as the unintended consequences of interdependent individual actions, yet not of human design. Such an interpretation highlighted the resulting institutions, or the processes leading to such consequences, and not the deviation from the linear purposive action. An astute exposition of the distinction between sociology and economics of the unintended in terms of research strategy was offered by James S. Coleman (1996: 387), one of the most skilled theorists in the UPE genre from the rational choice theory. According to Coleman, economics added a formal apparatus and demonstrated that equilibrium is possible (at least given the frame of reference).

This approach, which asserts that institutions are the unintended consequences of human actions, is highly embedded in political philosophy, history, and general economics. The classical illustrations pertain to Bernard Mandeville's, *Fable of the Bees: or, Private Vices, Public Benefits* (Schneider, 1990), Hume's theory of morality and justice as spontaneously generated orders, Ferguson's analysis of the evolution of social institutions, Smith's invisible hand, and Alexis de Tocqueville's progress of democracy.

The introduction of ISO is regarded as one of the greatest sociologically relevant contributions of the eighteenth century Scottish Enlightenment. Ramifications of its premises can be followed up in Georg Wilhelm Friedrich Hegel's 'cunning of reason,' as well as in Karl Marx's and Friedrich Engels' treatments of unintended consequences which are revealed as fatal contradictions. Particularly, the invisible-hand metaphor is commonly traced to Mandeville's fable. As it occurred rather sporadically in Smith ([1759]1976, [1776]1975, [1795]1982), its original meaning and background continue to be an issue. Important however is the fact that it evolved in symbiosis with the spontaneous order perspective and contributed to the development of the broader ISO.

In addition to the integration of the intellectual luggage of the invisible-hand notion, the spontaneous order theory found its cues in the works of ancient Chinese philosopher, Chuang Tzu, and the school of Salamanca's writings on economics in the late medieval period. This was followed by the strong contributions from the Scottish school, and from the nineteenth century onward, the compact developments of modern economists and political philosophers, most vividly from the Austrian School of Economics. Carl Menger's explanation of the spontaneous emergence of 'organic phenomena' served as the start of the latter contribution. Further, the twentieth century witnessed a proliferation of ISO explanations as well as an abundance of their critical accounts. In addition to Menger's explanation of the emergence of money, the most prominently referred to processes are Thomas Schelling's model of racial residential segregation, Ludwig von Mises's explanation of the formation of the medium of exchange, Friedrich A. Hayek's 'catallaxy' (i.e., spontaneous market order – see Barry, 1982), and Robert Nozick's account of the rise of the ultraminimal state.

With regards to the theoretical essence of ISO, this was comprehensively depicted in Nozick's (1974, 1994) presentation of the 'invisible-hand' and 'hidden-hand explanations,' and Hayek's ([1976]2003) development of the theory of spontaneous order. According to Nozick, in the invisible-hand explanation, a designed institution is shown to be the outcome of the interaction of actors having no such overall goal in mind. Further, in the hidden-hand explanation, an apparently accidental institutional structure is shown to originate from intended design. In the case of Hayek's treatment, the theory of spontaneous order was used as an argument in the programmatic opposition to the market socialism and central planning models.

As matters currently stand, the relation between the two concepts (the invisible hand and spontaneous order) is unclear, particularly as the former is subject to reinterpretations. Seemingly, the employment of one term over the other seems to be a matter of intellectual taste and background rather than of a straightforward delimitation of separate characteristics.

Current Refinements and Changes in Focus over Time

Although a comparative account of the contributions by Merton to the sociology of the unintended and the legacy of Smith and the Scottish Enlightenment in economics of the unintended are yet to be written, some elements could be pointed out still.

Merton is credited with the introduction and quite successful initial treatment of several concepts, such as unanticipated consequences of action, purposive social action, manifest and latent functions, self-fulfilling and self-defeating prophecy, boomerang effect, Matthew effect, and serendipity

pattern (Sztompka, 1986, 2011). The application area of these terms ranges from unanticipated consequences of purposive social action to cumulative and aggregate effects.

In comparison, Smith is basically associated with the invisible-hand metaphor – a term of appealing designation that was integrated as element of the Scottish Enlightenment's ISO perspective, and further evolved with the Austrian School of Economics. Moreover, the development of this thesis blurred the distinction between economics of the unintended and general economics, not to mention the fact that it pertained to programs outside these two fields (such as philosophy, public policy, biology, and more recently, the naturalistic philosophy of science). Such a strong connection between the UPE problem and particular schools of thought is lacking in the sociology of the unintended. Here, it is rather witnessed the strong consequential appeal of certain subdisciplines, sociological theories, and authors linked with their formulation.

As far as current sociology is concerned, the further prevalence of UPE can be witnessed in the more or less critical extension of Mertonian notions. The perspective is also common to rational choice sociology, analytical Marxism, and economic sociology. The Mertonian conceptual luggage notwithstanding these recent treatments should not be perceived as sole footnotes to Merton's legacy. They belong to consequential authors in their own right, who also benefited from other intellectual influences. Their works advanced the articulation of other dimensions which should be taken into account, in addition to the one of intentionality, when analyzing the unintended consequences of action – see Jon Elster's (1990) discussion of the issue of recognition and functionality, and Baert's (1991) dimensions and modes of unintended consequences. They sophisticated the classification of consequences to the extent that Merton's original treatment of unintended effects became just one of the variants being mentioned – see Portes's (2000, 2010) linear purposive action and alternative behavioral patterns. In addition to rendering and articulating the intellectual heritage of the sociology of the unintended, the sociologists also became more careful and candid in indicating that the notion of unintended does not imply strictly 'undesirable' or 'unexpected' outcomes (Boudon, 1982).

Despite this element of zooming out from the unexpected and undesirable, sociology further reproduces the interest in unexpected consequences of purposive action – whether individual or collective – and in the paradoxical and perverse character of the outcome – see Portes's (2000) 'sociology as analysis of the unexpected,' as well as the 'stronger definition' of Raymond Boudon's 'perverse effect' (Van Parijs, 1982). This preoccupation with the counterintuitive and paradoxical is also visible in accounts dealing with aggregate and cumulative effects – see Elster's (1978) 'counterfinality' and Coleman's (1994) 'social anomalies' brought about by seemingly rational behavior. In addition, it also transpires in the recent theoretical recovery of the paradox of consequences in Weber's work (Cherkaoui, 2007).

When it comes to the state of the art in ISO, two lines of development stand out. The first one pertains to the reevaluation of intellectual roots and the initial meaning of invisible-hand mechanisms in Smith's work (see for instance, Viner, 1972; Rothschild, 2002), as well as to critical perspectives regarding the use of this concept in economics (Barry, 1985; Aydinonat, 2008; Samuels et al., 2011). The reassessment endeavor is impressive and there is no real precedent of such criticism toward related concepts in sociology.

The second notable path is the further refinement of ISO. The general trend comes from interpretations which focus on end-states to rather abstract models, explicating the processes involved in the transition to unintended outcomes – for a review of models of institutions as unintended consequences of human actions in game-theoretic literature and agent-based computational economics, see N. Emrah Aydinonat (2008). Another angle for ordering the literature is through the lenses of Edna Ullmann-Margalit (1978a,b) who framed the evolution of the invisible-hand explanations from nonevolutionary models (the classical invisible hand) to evolutionary ones that became ideologically used against liberals and social planners. She distinguished between aggregate and evolutionary models – the former regarding the occurrence of social institutions, the latter concerning their maintenance (see also Hamowy, 2008).

As stated, according to Nozick (1974: 19; 1994), the invisible-hand explanations depict accounts of "what looks to be the product of someone's intentional design, as not being brought about by anyone's intentions." Although launched within political philosophy, this term has great theoretical potential in both economics and sociology. First, it integrates various treatments of the unintended in these disciplines. Second, it resonates theoretically with the concept of mechanisms, which itself emerges as one of the most relevant intersections between contemporary sociology and economics of the unintended (Cowen, 1998). Hence, there are indications that some of the recently launched notions might provide a common framing across academic disciplines which, in spite of a discursive consciousness claiming a common heritage, studied the phenomenon of the unintended rather in isolation.

Alternative and Emerging Directions in Theory and Research

Still the influence of UPE within sociology and that of ISO within economics should not be taken as thoroughly dominating the treatment of the unintended in these two fields.

When considering sociology, we see that manifestations of ISO enjoy more than an occasional occurrence – see the treatment of the emergence of social order from individual actions in rational choice theory and methodological individualism for instance. The peculiarity of the sociology of the unintended is not the absence of the social order problem (it builds after all on the tradition of the invisible-hand idea), but the fact that it inherited the tendency to qualify the unintended as unexpected and singular, sometimes even as unwanted, and focused on social action and the frustrations of actors' interests.

On the other hand, there are also sociological treatments which tried to dispel the approach that frames the unintended as unexpected. Arguably, the first sociologist to have normalized and discussed unintended consequences as a universal component of social life is Norbert Elias (see Mennell, 1977; van Krieken, 1998: 50). Following, Giddens's (1984) theory of

structuration offered a related demystification of the phenomenon. Inspired by his teacher Elias, Giddens depicted the unintended as recursive side effects which are further constitutive of the circumstances of social action.

In terms of contemporary approaches to the unintended via the side effects, the most vivid manifestation is the 'risk society' angle, within the broader reflexive modernization theory. This framed the 'unintended (second order; institutional) side effects' as consequences of modern social institutions which result in new conditions that call these institutions into question in the context of the second modernity (Beck et al., 2003: 14–15). Here, the "'meta-change' of modern society results from a critical mass of unintended side-effects" (Beck et al., 2003: 2).

The impact of the risk-society paradigm on the sociology of the unintended is manifold. Worthy to note is the fact that it made the concern with unintended consequences of social intervention (modern developments and projects in particular), and the unanticipatable outcomes of collective processes running blindly, visible within mainstream theoretical sociology. Furthermore, it promoted the topic of 'side-effects of side-effects' – e.g., the 'politicization' of side effects and the manner in which the unintended effects result in 'institutional turbulence' and legitimacy debates in global environmental politics (Beck et al., 2003: 14–15).

In Beck's 'first modern society,' he depicted the side effects in a similar manner to externalities within economics. There are two nuances in economists' definition of these. The first one presents the situation when "the activity of one entity (a person or a firm) directly affects the welfare of another in a way that is outside the market mechanism" (Rosen, 2002). Commonly, it is distinguished between positive (e.g., knowledge) and negative externalities (industrial pollution). The second nuance denotes "all the connections, relations, and effects which agents do not take into account in their calculations when entering into a market transaction" (Callon, 1998: 16). These definitions do not quite exclude each other. Importantly however, they presuppose distinct research focuses and conceptualizations in the analysis of the unintended.

In the former interpretation, the spotlight is on the initial intention. This is broadly understood as overall interests of the third party (who is not involved in the original transaction) and the perception of the desirability of the effects for the actor who was not accounted for (positive/negative/neutral). Depicted in these terms, the externalities resemble the side effects from the contemporary sociological discourse on unintended consequences. For economics, these are linked with market failure and pose a theoretical and ideological challenge to the ISO idea.

When it comes to the second framing, this concentrates on attempts to anticipate and include the effects of transactions in actors' calculations and negotiations. The point of interest is less the intention of the action and more the framing of the transaction and the contract. Such activities have the potential to become visible-hand processes, while the invisible-hand concept is linked to market failure. In reference to Ronald H. Coase's (1960) theory that externalities are the results of transaction costs, such understanding differentiates two categories of economic events: 'outcomes generated by encompassing contracts and externalities not covered by contract' (Cowen, 1998: 133). Tyler Cowen considered that this classification would overmatch the one of intended and unintended consequences altogether.

This type of perspective on externalities catches this double theoretical move toward depicting the unintended and negative consequences of collective phenomena, and toward researching the issue of their recording and inclusion in the calculation of costs and negotiations between actors. In other words, this is a research path preoccupied with advancing various strategies (from public to private) of internalizing the negative externalities (Callon et al., 2009) – a common preoccupation for economists and sociologists of the unintended alike.

The Unintended Consequences of Purposive Social Intervention

The recent trend in the study of unintended consequences in sociology and economics introduced the research of the unexpected via the side effects of modernizing programs. In somewhat more radical approaches, these side effects were shown to lead to surprises, paradoxes, and perverse effects of public policy, regulation, and high technology (Sieber, 1981; Brooks, 1986; Thompson et al., 1990; Grabosky, 1995; Tenner, 1997; Hood and Peters, 2004; Roots, 2004; Margetts et al., 2010; Winczorek, 2011). The case studies and conceptual tools advanced by this genre consider the unintended consequences of purposeful intervention. This means that they analyze consequences of attempts to effect social change. According to Sieber (1981: 9), "the term *social intervention* denotes any sort of deliberate effort to alter a human situation in some desired direction, such as a welfare program, a military expedition, an organizational structure, or a law." Although the study of unintended consequences of social intervention has a predilection for the paradoxical and perverse outcome, there are also analyses of phenomena which do not run as explicitly counter to the intentions of the institutional change initiators (Wildavsky, 1980; Pawlak, 2011).

Generally, the study of unintended consequences of purposeful intervention is an investigation field for public policy analysis, planned organizational change, evaluation research, social problems, and the analysis of the impact of high technology on society. In addition, it also surfaces in particular areas of sociology, such as applied sociology, and urban and environmental sociology. From a theoretical and conceptual point of view, it is evidently closer to sociology than to economics of the unintended. The theoretical apparatus builds on sociological framings of the unintended, yet it also advances potent original formulations and classifications. Overall, the observation that the discourses about unintended consequences and risks are socially constructed and are culturally embedded stands out. In addition to the issue of emergence, the studies on outcomes of social intervention also focus on the management of the unintended by various organizational and regulatory regimes.

When incorporating sociological insights, the research on unintended consequences of social intervention mainly builds on Herbert Spencer's application of the idea of regressive effects to governmental programs, on Weber's thesis of the indirect

and unintended effects of rational ascetism, and on Merton's classification of limitations to the anticipation of consequences of social action. The most illustrative author who incorporated and critically approached the sociological knowledge of unexpected outcomes is Sieber (1981). He advanced seven conversion mechanisms which can lead to regressive consequences of purposeful intervention. In addition to such rather traditional references, the analysis of social intervention also rejuvenated the interest in Simmel's and Edward A. Ross' sociologies of the unexpected, and showed their relevance for studying unintended consequences in 'high modernity' and 'knowledge society' (Gross, 2003, 2010).

When it comes to conceptual framings which are divergent from the sociological undertaking, the analysis of risks and unintended consequences by employing cultural theory stands out (see Douglas and Wildavsky, 1984; Thompson et al., 1990; Douglas, 1992). Though this perspective is still pretty much under construction, its prospects of development are quite promising, especially in light of the recent reactivation of the theory by Christopher Hood (2000; Hood and Peters, 2004). The grid-group analysis of unintended consequences has potential because it reveals the rhetorical structure of perspectives on risks and unexpected effects, and the fact that such discourses are culturally embedded.

Concerning the rhetoric of unintended consequences, the most powerful theorist of social intervention by far is Hirschman (1991). This author's input is manifold – see, for example, the perverse effect as a particular thesis of the conservative-reactionary response to purposeful intervention. Further, Hirschman (1975) also pointed out that the rhetorical sensitivity of organizations to particular types of unintended consequences is determined by the overall self-perception of their effectiveness (see discussion of 'fracasomania' – the failure complex), meaning that the social scientists have to be aware of possible exaggerations regarding the pervasiveness of unintended consequences and the implications of such discourses.

The research of unintended consequences of purposeful intervention also points to the management of unintended consequences and risks (Wildavsky, 1988). Notably in this regard is Karl Weick and Kathleen Sutcliffe's (2007) study of high-reliability organizations' (HROs) response to critical situations, and Diane Vaughan's (1996) analysis of the tendency to normalize the unexpected in the 1986 NASA Challenger disaster – see also Charles Perrow's (1984) normal accident. Comparatively to the policy analysis of surprises and paradoxes, the impact of high technology discusses the unexpected and accidents occurring in society.

Observably, the unintended effects of modernization programs and high technology is the social site where the three main types of investigation of unintended consequences – i.e., pertaining to purposive social action; to human action, but not human design; and to purposive social intervention – can most probably bridge a common conceptual framework. It is also noticeable that in spite of common intellectual luggage (traceable to classical authors), and unsystematic attempts to reach a more integral perspective, the three fields on the unintended evolved rather autonomously. The materialization of theoretical affinities that is recently discernable is based on the openness of sociology to influences from economics of the unintended, and also on the refinement of some sociological and philosophical concepts by the policy analysis of the unintended. This theoretical turn is somehow unexpected in light of the fact that sociology has a conceptual vocabulary similar to one of the policy analysis, but anticipatable given the attractiveness of the confident analyses put forward by economics.

United Nations and its Agencies

Janice W Wetzel, International Association of Schools of Social Work, United Nations
Nancy E Wallace, World Federation for Mental Health, United Nations

© 2015 Elsevier Ltd. All rights reserved.

Abstract

As the social work profession increases its international presence in the twenty-first century, involvement with selected United Nations (UN) bodies is vital. The interface between social work and UN agencies that are most relevant to the concerns of both will be addressed. Important information regarding the UN will be presented to enable knowledgeable participation. Examples of social work advocacy over the years, likely to remain relevant for decades to come will be described, alongside recommendations for social work's future involvement.

The United Nations' Social Agenda

The social agenda of the United Nations (UN) and that of the social work profession are closely aligned. Both are concerned with a broad range of psychosocial issues that span social justice and human rights, promotion of peace, economic and social development, eradication of poverty, disaster relief, the advancement of women, and support for other marginalized populations including children, older people, immigrants, and disabled people (Dominelli, 2010). The promotion of health and psychosocial well-being are also shared concerns. While each UN agency may focus their efforts on particular areas of involvement, one should be aware that they are all committed to human rights regardless of specialization (Healy and Link, 2012).

The UN system is comprised of the General Assembly, the Security Council, the Economic and Social Council, and its specialized agencies, funds, and programs (Wilson, 2012). The UN Charter calls for formal relationships between non-governmental organizations (NGOs) and the UN like those representing international social work and social welfare. The work of NGOs includes consulting with Member States, providing technical expertise, advocacy, participating in joint operational projects, disseminating information, and raising awareness between the UN and civil society. International social work organizations are among these NGOs.

International Social Work Organizations at the UN

The International Association of Schools of Social Work (IASSW), the International Federation of Social Workers (IFSW), and the International Council on Social Welfare (ICSW) were all founded in Paris in 1928 at the First International Conference on Social Work. These global social work organizations, the largest in the world, hold consultative status with the Economic and Social Council (ECOSOC) at the UN and with the Department of Public Information (DPI), among others. All three organizations participate as NGOs in principal UN locations including New York, Geneva, and Vienna and have regional offices globally.

IASSW promotes the development of social work education throughout the world and develops standards to enhance the quality of social work education and research in 3000 schools of social work at tertiary level in 74 countries. They are concerned with social justice and social development through human rights-oriented policy and advocacy activities. IASSW was the first social work organization to acquire Special Consultative Status in 1947 and was present at deliberations on the Universal Declaration of Human Rights (Healy, 2012).

IFSW provides a global voice for the profession with over 750 000 members in 90 countries. They strive for social justice, human rights, and social development through the promotion of social work and best practices. IFSW is affiliated with the United Nations Children's Fund (UNICEF), and like its sister organizations, also works with the World Health Organization (WHO), the United Nations High Commissioner for Refugees (UNHCR), and the Office of the High Commissioner for Human Rights (OHCHR) (Hall, 2012).

ICSW promotes social development, social welfare, and social justice undertaken by tens of thousands of independent community organizations in 70 countries that work with people in poverty, hardship, or distress. Its membership is made up of multiple professions, including social workers. They involve a network of major international organizations, as well as people who are themselves experiencing hardship, working in their own communities. ICSW serves a range of vulnerable, marginalized people across the life span in numerous cultures. Their work with the UN has long been collaborative across governments, missions, and NGOs (Correll, 2012).

Together, these three organizations launched a Global Agenda for Social Work and Social Development that was presented at the UN at the 29th Annual Social Work Day in March 2012. They agreed on an action agenda to prioritize collaborative activities between 2012 and 2016 around four themes: promoting social and economic equalities, advancing the dignity and worth of all people, working toward environmental sustainability, and strengthening recognition of the importance of human relationships. Action steps will be reported annually through the Global Agenda Observatory (Zelenev, 2013). A European Observatory for Social Work and Social Development was launched in 2013. There will be a special supplement on the Global Agenda presented in 2014 that will be used to provide data to influence the UN.

As a first subsequent effort, IASSW, ICSW, and IFSW made a joint Statement for the High Level Segment at the Annual

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28098-7

Session of ECOSOC held in July 2012 in New York, addressing the Annual Ministerial Review theme, "Promoting productive capacity, employment and decent work to eradicate poverty in the context of inclusive, sustainable and equitable economic growth at all levels for achieving the MDGs."

Social Work Day at the UN was founded under the aegis of IFSW in 1983. It became a joint enterprise with IASSW in the early 1990s. Over the years, the event has attracted thousands of students and professionals. It is designed to educate social workers and students about the UN and the UN about social work. The themes of Social Work Day have emanated from the shared concerns of the UN and the international social work community. Topics have ranged from practice and policy issues regarding human rights, women, children, families, indigenous populations, mental and physical health, social development and disasters – both natural and artificial (Dominelli, 2012). In recent years, a Global Social Work Student Day, organized by students, has accompanied this event.

Education of the community, UN advocacy, and social action are important social work roles. Examples of social workers' involvement include providing training, workshops, and curriculum development for the profession on humanitarian, social, and economic development issues; and utilizing international human rights conventions to support local advocacy efforts. They also participate in UN World Summits on social development, sustainable development, women, HIV/AIDS, xenophobia, climate change, and aging. They write policy statements and make presentations to governments and the UN through the NGO forums associated with these events.

Social workers engage in activities under the aegis of the UN Conference of NGOs (CoNGO), the umbrella organization that facilitates the participation of NGOs in the UN system. Affiliation allows social workers and other NGOs to address themes and issues through participation in pertinent NGO committees. Social workers, for example, were instrumental in founding and providing leadership for the UN NGO Committee on Mental Health. Its creation has fostered collaboration among NGOs that has strengthened efforts to bring mental health issues to the global agenda at the UN. They introduced World Mental Health Day to the UN, which formally incorporated the event in its annual calendar of celebrations. A social worker delivered the first address concerning women and mental health at World Mental Health Day in 1996. The committee has been an important vehicle for advocating social work concerns.

Social work educators have established schools of social work where none existed before, e.g., Argentina, the Cameroons, and Vietnam; undertaken study trips in countries to address social issues such as trafficking in women and children, aging populations, organized crime, health and mental health, economic crises, natural disasters, and other issues that require urgent attention and benefit from social work perspectives.

UN World Conferences and Summits

Social work NGOs have been involved with the UN for decades. The launching of world conferences and on-going events since 1990 has fostered increased opportunities for advocacy and decision-making. Social workers provided leadership at these conferences, serving on numerous planning committees and drafting policies, conducting global meetings and panels, and coordinating the conferences themselves in some instances. If the profession is to be a viable participant in the twenty-first century, social work leadership and visible involvement will be required at all appropriate UN ventures.

There are nine World Conferences that have influenced governments and NGOs. These conferences continue to have periodic follow-up meetings to evaluate progress on the action plans and integrate emerging issues in order to plan for the future. In-depth information regarding each conference is available on the Internet. World Conference action plans indelibly changed how development has been conceptualized. While economic and social policies previously excluded the reality of people's lives, all development programs are now people-centered and focused on eliminating poverty and fulfilling basic needs, alongside realizing human rights, investing in health and well-being, education and training, and improving the status of women. Training and technical consultations have been replaced by capacity building concepts and sustainability. Social work is well-suited to join in such a participative model. See http://www.un.org/geninfo/bp/intro.html for a comprehensive discussion of these new approaches.

Millennium Development Goals

Any discussion of the UN and its priorities of relevance to social work must cover the Millennium Development Goals (MDGs). Building on the work of earlier World Conferences, the eight MDGs were launched in 2000 by consensus of member states for the purpose of reducing extreme poverty by 2015 and aimed to:

1. Eradicate extreme poverty and hunger;
2. Achieve universal primary education;
3. Promote gender equality and empower women;
4. Reduce child mortality;
5. Improve maternal health;
6. Combat HIV/AIDS, malaria, and other diseases;
7. Ensure environmental sustainability; and
8. Develop a global partnership for development.

A 2014 MDG report indicates that progress has been made on some fronts, but the MDGs will not be fully realized by the target date. Consequently, governments in cooperation with civil society are developing a post-2015 agenda to meet today's challenges. This bears in mind, lessons learned from the MDG framework, while taking into account current realities that did not exist at the start of the millennium. While the importance of the MDGs is not disputed, there are many who regret the absence of other key concerns such as the escalating global issues of aging, mental health, violence, and disasters. NGOs are advocating for their inclusion. Social workers have important roles to play in the post-2015 process to ensure the goals are met and social work interests are included in it.

Sustainable Development Goals

In July, 2014, the UN Open Working Group (OWG) of the General Assembly concluded 18 months of consultations and

negotiations to produce an Outcome Document which contains 17 proposed goals and 169 related targets creating the recommended framework for the Sustainable Development Goals (SDGs) for post-2015. Health is highlighted in Goal 3: "Ensure healthy lives and promote wellbeing for all at all ages." This includes a target to "reduce by one-third premature mortality from non-communicable diseases through prevention and treatment, and promote mental health and wellbeing" (SDGs, 2014). This should be of particular importance for social work practice, advocacy, and education.

Non-Communicable Diseases

On the threshold of the post-2015, SDGs, one of the greatest challenges, is in the area of global health. Of particular interest to social workers are Non-Communicable Diseases (NCDs) which include mental and neurological disorders. In 2011, the General Assembly mandated a comprehensive review and assessment of the progress achieved in the prevention and control of NCDs. In July 2014, UN member states, the UN system, and civil society met for the UN NCD Review to assess the progress and gaps. Emphasis in the final outcome document focused on developing a set of commitments and actions for global and national implementation, prevention and treatment across the life span, mobilization of resources and recognition of NCDs as a priority in the post-2015 development agenda (NCDs, 2014). This critical emerging issue has important implications for social work and opportunities for collaboration with the UN and civil society in supporting and advocating for implementation, accountability, and civil society capacity building. A UN publication, The Global Conversation Begins: Emerging Views for a New Development Agenda, has been launched to assess progress (United Nations, 2013).

Post-2015

The year 2015 marks the 70th anniversary of the United Nations. It is both a target year and the 20th anniversary for a number of historic internationally agreed upon documents (UN Agreed Upon Documents, 2014). The close of the MDG process galvanized a post-2015 agenda to the year 2030. This time, the focus is on SDGs, a more inclusive, intergenerational perspective that also aligns with Rio + 20, the world's Sustainable Development Conference held in June of 2012.

The 20th Anniversary of the Copenhagen Declaration and Summit on Social Development is also a 2015 event in which social workers are engaged. Concerns about inequalities and advocacy for a social protection floor will continue to be crucial undertakings. The end of poverty continues to be a worldwide post-2015 objective.

The year 2015 is also the 20th anniversary of the Beijing Platform for Action, passed in 1995 at the 10-year follow-up to the end of the Decade of Women, also called the Fourth World Conference on Women. ECOSOC will review the 12 essential areas of concern that are designed to achieve the goals of gender equality, development, and peace. It has become clear over the last two decades that there are forces that are devoted to rolling back the gains of the international women's movement. Therefore, it was decided not to hold a global women's conference as had been done previously, but to launch a review of every government's progress and challenges to making the Beijing Platform for Action a reality. UN Women is committed to ensuring that gender equality is a fact across the world, locally, nationally, and internationally.

Convention on the Elimination of All Forms of Discrimination against Women

A core principle leading to Beijing was based upon CEDAW, the Convention on the Elimination of All Forms of Discrimination Against Women, created at the middle of the Decade of Women in Copenhagen. CEDAW is essentially a Bill of Rights for Women. To date, 187 out of 194 countries have ratified and signed the agreement. Those that have not are the United States, Iran, Sudan, South Sudan, Somalia, and two small Pacific Island nations (Palau and Tonga). There is a US movement designed to provide pressure for implementation at the national level that include Cities for CEDAW and CEDAW 2014. Attention will also be given to the many governments who have signed on but are found wanting in its execution, a major concern of the United Nations and the women of the world (CEDAW, 2014).

UN Agencies Relevant to Social Work

Economic and Social Council

ECOSOC, the body most relevant to social work at the UN, is concerned with the world's economic, social, and environmental challenges. Policies are recommended following discussion of pertinent issues by member states. Meetings are held throughout the year with prominent academic and business leaders, including 3200 registered NGOs in consultative status with ECOSOC.

NGO affiliation is assured by the Charter of the United Nations, Article 71. Eligibility requirements, rights, and obligations are governed by ECOSOC resolution 1996/31. Consultative status is granted by ECOSOC upon recommendation of the ECOSOC Committee on NGOs. Every year, at meetings convened by ECOSOC, NGO representatives including social workers are invited to provide technical expertise, interventions, and position statements that address the topics being discussed. One example is the "Intervention on Participation in Poverty Reduction," written by the IASSW representative to the UN Commission on Social Development.

Department of Public Information

DPI was established to promote UN global awareness and understanding using media including publications, radio, TV, the Internet, and video conferencing. DPI partners with diverse audiences throughout the world, including NGOs at the UN in New York where it maintains an NGO Resource Center. During weekly briefing panels, topics being highlighted at the UN are discussed. NGOs are given the opportunity to affiliate with DPI and access the UN just as they do through ECOSOC. Both

IASSW and IFSW are affiliated with the DPI. DPI also coordinates an annual, well-attended international conference in various locations around the world. These meetings are planned by a large group of NGO volunteers, including social workers, in cooperation with UN staff.

Department of Economic and Social Affairs

Department of Economic and Social Affairs (DESA), the think tank for the UN, works closely with ECOSOC and other divisions. The Social Integration Branch, Division for Social Policy and Development, is particularly relevant to social work. This provides substantial intergovernmental support at the UN, while facilitating international cooperation on social and economic development issues. Key concerns are hunger and malnutrition, sustainable development, disability, indigenous people, employment issues, and social protection. Their work includes aging, youth, family, and inclusive policy issues that are submitted to the UN Commission for Social Development, the ECOSOC, and the General Assembly.

DESA's mandate calls for increasing capacities in developing countries so that they might better function and contribute nationally and internationally. Capacity development is the process by which people, organizations, and societies become self-sustaining, capable of achieving their own goals. Building capacities increases the likelihood that the MDGs and post-2015 development agendas will be realized. Social workers, educated to facilitate capacity building, are natural partners.

United Nations Development Program

United Nations Development Program (UNDP) is the UN's global development network. UNDP operates on multiple levels – local, national, regional, and global – in 177 countries and territories, and within the UN itself. Like social workers, UNDP advocates for change and helps people to connect to resources at local, regional, and country levels. Partnership is at the center of all aspects of their work, which focuses on solutions to development challenges as voiced by people themselves. The protection of human rights and empowerment of women are embedded prominently in their mission.

UNDP is also concerned with capacity development as an evolving approach based on research. They have identified four drivers of change that yield significant capacity and are assessable: institutional arrangements, leadership, knowledge, and accountability. UNDP was instrumental in setting the standard for gender mainstreaming at the UN. Thus, all policies, practices, and programs are assessed through a gender-specific lens. UNDP and social work are kindred spirits. International social work organizations could engage further with the UNDP Resident Representative in each country to strengthen their voice in UN development activities.

UN Human Rights Council

The mandate of the UN Human Rights Council (HRC) is to promote and protect human rights worldwide, identifying and developing responses to challenges and violations. The main office of the HRC, located in Geneva, Switzerland, is supported by the OHCHR. OHCHR provides the UN with research, education, and advocacy. Assistance is also given to governments. OHCHR helps to implement social justice, legislative reform, and electoral processes to facilitate human rights standards. Consistent with the creation of the UN Charter, the OHCHR is charged with mainstreaming human rights by incorporating a human rights perspective in all UN programs. To that end, it partners with governments, civil society, and all UN bodies and international organizations, including NGOs.

Social workers have been active with HRC and OHCHR, advocating extensively on human rights concerns, including writing manuals on human rights and providing policy statements and consultations on human rights violations. IFSW's and IASSW's policies on human rights are utilized as the basis for advocacy with these UN entities. For example, IFSW's policy on refugees addresses their physical needs for food, shelter, clothing, and health, alongside psychosocial needs essential to human well-being. Other social work interventions have included human rights coalition building with other Consultative NGOs. IASSW and IFSW collaborated with the UN in 1994 on a Human Rights Manual for educating social workers (UN, 1994). Social workers have long encouraged the inclusion of international human rights in social work curricula (Ife, 2012; Wronka, 2007, 1995; Reichert, 2007; Wetzel, 2000). A number of the world's schools are becoming totally human rights oriented.

Office for the Coordination of Humanitarian Affairs

Office for the Coordination of Humanitarian Affairs's (OCHA) mandate includes coordination of interagency decision-making in response to complex emergencies. Participants include NGOs and the International Federation of Red Cross and Red Crescent Societies, as well as the UN agencies. Without their expertise, responses may be fragmented and inappropriate. Relief is needed in the short term, providing necessary resources and meeting basic human needs. Disaster response must also engage in sustainable long-term efforts and be grounded in a human rights orientation and research to be effective.

Social workers should be key players in the dissemination of information and coordination of responsible disaster policies and services on the ground and have an important role to play in humanitarian aid work (Tan, 2009). Social work has a comprehensive perspective regarding psychosocial responses to natural and artificial disasters ranging from hurricanes and tsunamis to conflict-related emergencies and the infrastructures to ensure professional accountability and deliver training (Dominelli, 2013a). Like OCHA, social workers advocate for the rights of people in need and can be partners in fostering sustainable programs. They are well positioned to ensure support to meet clients' needs, strengthen leadership coordination and evidence-based humanitarian decision-making, planning, and resource allocation.

Social workers have been at the forefront of climate change awareness and disasters for many years, including issuing policy statements on the subject at the United Nations (Dominelli, 2012). Social workers at the UN in collaboration with other NGOs have addressed the impact of climate change on mental health and psychosocial well-being (Weissbecker et al., 2007).

Social work practitioners and academics have been involved in disaster response and preparedness, providing education and training for the UN, governments, universities, municipalities, first responders, and health care workers (Desai, 2007). The Inter-Agency Standing Committee (IASC) under the auspices of OCHA is mandated to improve delivery of humanitarian assistance to populations affected by natural disasters, conflict-related emergencies, global food crises, and pandemics. Social workers have assisted IASC in producing a series of guidelines for responding to humanitarian crises. These have included gender-based violence, disasters, social development, and psychosocial interventions. The IASC Guidelines for Mental Health and Psychosocial Support in Emergency Settings are widely used and have been lauded worldwide as exemplary practical psychosocial interventions that eliminate stigma, inappropriate practices, and policies and integrate a human rights approach.

UN Women

The UN Charter (United Nations, 1945) and the Universal Declaration of Human Rights (United Nations, 1948) reflect the United Nations' long-standing commitment to the plight of women. In 2010, in response to the UN reform agenda, the United Nations General Assembly created UN Women, the UN Entity for Gender Equality and the Empowerment of Women. In doing so, it provided an umbrella organization equipped to merge resources and mandates for greater impact. The offices involved in the merger were: the Division for the Advancement of Women (DAW), International Research and Training Institute for the Advancement of Women (INSTRAW), Office of the Special Adviser on Gender Issues and Advancement of Women (OSAGI), and United Nations Development Fund for Women (UNIFEM). Information is available on the UN Women website.

Despite concerted efforts and progress made on behalf of women over the past decades, UN Women notes that gender inequalities are entrenched throughout the world, denying women basic human rights (United Nations, 2009, 2006). Not only is this disparity oppressive to women, but it also affects their families and communities and has vast socioeconomic ramifications. UN Women is not alone in recognizing that empowering women fuels thriving social and economic development. Social workers have long called for the advancement of women and their human rights (Reichert, 2007; Wetzel, 1993). Curricula in many countries entail awareness of the situation of women and girls, and the importance of supporting and facilitating changing attitudes toward them (Dominelli, 2013b). Social work and UN Women are natural partners.

United Nations Children's Fund

UNICEF, operating in 190 countries, is dedicated to the rights of all children, having the global authority to influence decision-makers at the highest levels, and establishes relationships with grassroots partners, including young people, who have innovative ideas that need assistance to turn them into reality. The organization is the standard bearer for the Convention on the Rights of the Child, essentially the bill of rights for the world's children. UNICEF is committed to removing the challenges that block women and, in turn, the development of children, whether concerned with poverty, malnutrition, violence, preventable disease, or discrimination. Recognizing that girls are at risk throughout the world, UNICEF works to promote their education as fundamental to their advancement and well-being.

Social workers representing many NGOs have been involved with UNICEF for years. In 2012, UNICEF commissioned a Child Protection Systems Strengthening paper that consolidates current thinking and lessons learned, including the need for a strong child protection workforce (McCaffery et al., 2012). Participation of social workers at UNICEF-sponsored conferences has led to other key initiatives by international social work organizations. The journal, *International Social Work*, for example, published special issues on Globalization/Indigenization (Lyons, 2010) and on Children's Rights in Africa (Sewpaul and Matthias, 2013).

Working Group on Girls

The Working Group on Girls (WGGs) is dedicated to advancing their rights and status. Their efforts focus on the implementation of the commitments to girls' rights that have been established by international agreements. Advocacy in the form of policy statements, program development, and resource allocations includes the participation of girls as agents of change in their own families and communities.

World Health Organization

WHO is the coordinating authority for health within the United Nations system. It provides leadership on global health and mental health issues, shapes the research agenda, sets norms and standards, and provides best practices based upon evidence-based policy research.

The WHO's Constitution states that "health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1946, 2006). They recognize that depression affects more than 350 million people of all ages, in all communities, and is a significant contributor to the global burden of disease. Women worldwide are twice as likely to experience depression as are men, regardless of economic status, racial, or ethnic background. By the year 2020, WHO predicts that it will be the second leading cause of disability, with women most affected (WHO, 2008).

In response to the escalating global mental health risk, WHO launched its Mental Health Gap Action Programme in Geneva. Although aware of needs in developed countries, its aim is to increase services for mental health and substance abuse in low- and middle-income countries (WHO MhGAP, 2008). At the core of mhGAP is the establishment of productive partnerships that address psychosocial interventions, including family- and community-based treatment and rehabilitation for depression, alcohol, and drug dependence. More social workers are needed in many developing countries and rural areas if their objectives are to be realized. Regardless of cultural differences, early intervention, basic education, and training of professional and lay people are essential (Wetzel, 2012).

WHO's most recent initiative is the development of the 2013–2020 Global Mental Health Action Plan, which is a transformative agenda on the global burden of mental disorders and the need for a comprehensive, coordinated response from health and social sectors at the country level. This provides an important opportunity for social workers to become more involved in psychosocial policy development and advocacy.

United Nations Educational, Scientific, and Cultural Organization

UNESCO is a specialized agency of the UN system, based in Paris. It is devoted to fostering peace throughout the world. Universal respect for social justice and the rule of law are advanced by promoting collaboration among nations through education, science, culture, and shared communication. Human rights and fundamental freedoms are core affirmations regarding race, sex, religion, and language.

UNESCO's celebrations during the 60th Anniversary of the Universal Declaration of Human Rights at its headquarters in Paris in 2008 provided a forum for diverse participants from governments, media, academia, and the private sector. Its central objective was to identify and acknowledge the most effective ways in which civil society was making a positive impact on respect for human rights. Under the aegis of the DPI, programs included a panel of experts on "International Community Mental Health Education: Human Rights-Based Grassroots and Professional Models" that involved IASSW as organizer and moderator. Panelists' shared messages included the empowerment of indigenous people as leaders; the creation of schools of social work in developing communities; and the unique relevance of social work in such communities.

UNESCO has objectives well suited to partnering with international social work education. Relying primarily on research, training, and teaching activities, UNESCO strives for the advancement, transfer, and sharing of knowledge. Technical cooperation encompasses the preparation and adoption of international instruments and legal recommendations that are consistent with social work goals.

Social Work Skills, Best Practices, and the UN

The following best practices are suggested for international social workers. Most are familiar to the profession, but the provisos may be thought provoking.

Psychosocial Perspective

The strengths perspective concerned with the resourcefulness and resilience of people, long embraced by social workers, is an appropriate global orientation, particularly when applied within a psychosocial framework.

Self-Determination and Cultural Relativism

Human rights in a global context should respect and embrace alternative cultural practices. Provided that the customs are not abusive, they can be very effective. While cultural sensitivity and cultural competence are essential social work values to be honored, cultural relativism must not overshadow human rights. When a local practice is abusive, even if it is accepted by the community, abuse in the name of self-determination is still abuse (NASW, 1997).

Human Rights-Based Social Work and Gender Mainstreaming

By adopting human rights as the foundation principle upon which all of social work theory and applied knowledge rest, social workers involved with individuals, families, small groups, large communities, or institutions will have a value-based tool in which to apply their knowledge and skills. Gender mainstreaming is the UN human rights method designed to ensure the appropriate assessment of practices, policies, and programs in terms of their disparate impact on girls and women and boys and men across the life span. If they are not appropriate for everyone, it is not appropriate that we engage in them (OSAGI, 2008).

Human Rights and Social Justice

Social justice is a significant but insufficient concept in that it is inherently associated with cultural mores that may limit one's rights. Human rights encompass social justice and transcend civil, economic, and political customs, in consideration of the basic life sustaining needs of all human beings, without distinction (NASW, 1997).

Capacity Building, Personal and Social Development

Many definitions of capacity building have emerged since the latter part of the twentieth century when the UNDP promoted capacity building to alleviate poverty as an international policy directive. Increasing the capacities of individuals through enhancing their potential ability and skills, so that they can become fulfilled members of society, is a shared objective with social work. Whether working with groups or communities, increasing culturally-appropriate self-awareness is a universal means of increasing self-esteem, so essential to personal development (UNDP, 2013).

Train the Trainers Model

Train the Trainers is a model that has evolved from the international women's movement in the developing world since the mid-twentieth century. It is designed to address the shortage of professionals, while empowering women to take charge of their own lives and futures. The model is also suitable for men. A participatory, non-hierarchical group-dynamic approach is taken whereby experts train leaders who in turn train others in an organization or community. They in turn train others, and so on. The approach has been used in comprehensive health programs, with factory workers, and micro-credit programs throughout the world (Femnet, 2013; Wetzel, 1993).

Participative Social Action Research and Programming

Participatory action research is a cyclical process that begins with diagnosing problem situations, planning action steps, and

implementing and evaluating the outcomes that in turn lead back to reassessment based upon data collected. The findings are applied to effective policy and programs relevant to the real world of participants. By including the vital input of stakeholders, the likelihood that studies will be implemented is increased. In the process, individuals, organizations, and communities each develop capacities that enhance success and development. The empowering participatory process of social action research is as effective an intervention as the end result (Powers and Allaman, 2012; Participatory Action Research Toolkit, 2010).

Social Work and Global Economics

It is recommended that social work education consider including more information on economics, particularly from a global perspective (Ortiz and Cummins, 2012; Staub-Bernasconi, 2007). Formerly grounded in a colonialization perspective, international development policy has progressed over the years to focus on the empowerment and inclusion of recipients. It is important that social workers understand the relationship between economics and social conditions, and the impact of economic policy on development policy. For example, HIV/AIDS donor nations have had strings attached that hamper recipients on the local level. Despite good intentions, Western governments, the World Bank, International Monetary Fund, and United States Agency for International Development have had to consider debt forgiveness in the face of growing poverty due to structural adjustment requirements (Lewis, 2005).

Social Work and the Social Compact

In developing countries where entitlements are often nonexistent, human rights are championed by NGOs (Gibney, 2003). Throughout the world, in recent years, the social compact that has provided a safety net for people in need has been waning. Social work can act as a catalyst to help to reactivate each nation's commitment on behalf of disenfranchised populations by encouraging social workers to join grassroots community coalitions. Everyone can learn from one another all over the world, appropriately transferring, adapting, and applying their hard-earned knowledge and skills to the problems in their own countries (Jones, 2007; Hokenstad and Midgley, 2004). Social workers and social work educators also must continue to teach students how to develop resources, build coalitions, engage in advocacy, and provide support and missing expertise where needed (Hokenstad, 2008). By doing so, the United Nations will find social workers to be invaluable partners.

Universities and Science and Technology: Europe

Abstract

Science and technology at European universities have changed substantially. With the emergence of a global knowledge economy, science (as basic research) and technology (as a product of applied research) are more tightly coupled to form the basis for national wealth creation. Universities are expected to provide well-trained scientists and engineers, new knowledge, and applied science. European systems of higher education have been challenged by these new economic conditions. State budgets are increasingly constrained. Ministries have been deregulating authority to the institutions. Information technology has influenced knowledge production and delivery. A more diverse student body has been seeking a university education as part of their life-long learning need. Globalization and international competition have pushed European universities to revise and reorganize their institutions. Consequently, academic science and technology are in a process of restructuring. New knowledge transfer strategies are emerging that aim at increased alliances between companies and universities. Research has become more interdisciplinary and problem oriented. Market-based funding develops as a system supporting industry-related as opposed to curiosity-driven research. More management capacity within universities is needed to deal with these changes. Overall, universities must refocus their mission in order to integrate knowledge production (research), knowledge dissemination (teaching), and knowledge application (outreach/service).

The role of science and technology at European universities has been undergoing tremendous changes (Etzkowitz and Leydesdorff, 1997; Zinberg, 1991). Given the increased importance of information technology and the emerging global knowledge-based economy, scientific research and development, as well as academic training, form the basis of national policies and institutional strategies to promote economic growth. As a consequence, universities are expected to respond to the need for well-trained scientists and engineers, new knowledge, and applied science (Zinberg, 1991). The industry and technology-oriented academic fields like engineering and business management find it easier to combine science (as basic research) with technology (as a product of applied research) in order to meet the new requirements of the economy and to raise additional funds. Other disciplines in the social sciences or humanities may have greater difficulty in maintaining a key position within universities and obtaining necessary resources (Slaughter and Leslie, 1997).

In order to understand the current trends in academic science and technology in Europe, it is important to describe the institutional varieties of universities. Trends in different European countries serve as a basis for analyzing new challenges for higher education systems. Consequences for the production and management of knowledge show the new imperative for the future, which emphasizes a redefinition of the relationship between universities, industry, and the state in Europe (Etzkowitz and Leydesdorff, 1997; Neave and Van Vught, 1991).

Academic Science and Technology in Europe

European systems of higher education consist of a variety of universities and colleges (Gellert, 1993; Teichler, 1996). On a very general level, two types of universities prevail: one of a comprehensive character and the other specializing in one field or area. The comprehensive university represents a conglomerate of different faculties, academic programs, and consequently a larger number of students. Specialized universities are focused on a particular academic discipline or field, such as business administration or engineering, with only one faculty and fewer students. Specialized universities tend to focus on applied research and professional training, thereby responding more easily to external needs of the labor market and private industry. Comprehensive universities are more likely to be dedicated to basic research and training (Teichler, 1996).

The modern European university which combines research and teaching emerged in the early nineteenth century and went through a lively period of transitions up to the present. The proliferation of fields (e.g., biotechnology, telecommunications, electronic commerce) and new institutional types (e.g., business schools, vocational colleges) have been based on the increasingly diverse research and education needs of national economies. In retrospect, this differentiation of functions appears to have been a consequence of the new requirements of the labor market and changes in the knowledge infrastructure (Etzkowitz and Leydesdorff, 1997). At the same time, the role of higher education shifted emphasis from social mobility to wealth creation (Nowotny, 1995). In other words, universities had to find new forms to translate science into technology, moving away from earlier concerns with liberal education and curiosity-driven research (Slaughter and Leslie, 1997). Many European governments and ministries have played a pivotal role in this shifting of emphasis in higher education systems by supporting universities through research money and other financial incentives (Etzkowitz and Leydesdorff, 1997).

These new trends in the social and economic context of universities have also changed the role of knowledge (Gibbons et al., 1994). Traditionally, institutions of higher education across the world have performed core missions and functions: knowledge production (research), knowledge dissemination (teaching), and knowledge application (service–outreach). For

universities operating in a social context of application, research has to accumulate not only disciplinary-based knowledge but also useful results for society. The reason for the increasing application–orientation of higher education systems, especially in Europe, has been mass higher education leading to new forms of knowledge production focusing more on a link between science and technology. As a consequence, the university has moved from an ideal model (i.e., social change) to a pragmatic model (i.e., wealth creation) (Gibbons et al., 1994; Trow, 1973).

In Europe, mass higher education not only entails a sharp increase in students, faculty, and institutions. Generally, it also implies increasing institutional diversity, organizational complexity, and academic heterogeneity. Also, public pressure has challenged the ideal of autonomous universities as 'ivory towers' and has called for more accountable institutions (Dill and Sporn, 1995). In the following section these challenges are analyzed more closely.

New Challenges for European Systems of Higher Education

Colleges and universities in Europe have become part of mass higher education systems because of expansion and diversification. Expansion refers to the large increases in student numbers in most European countries caused by public policies to provide education to a larger portion of the population. Diversification means mostly a binary system of higher and vocational education translating into different types of institutions for different target groups (Sporn, 1999). In this process, knowledge production and dissemination have become very important. "The driving force behind accelerated supply and demand of marketable knowledge lies in the intensification of international competition in business and industry. In many cases in-house research is no longer sufficient to meet competitive demands. In order to commercialize knowledge, firms have to look for new types of links with universities, government laboratories as well as with other firms" (Gibbons et al., 1994, p. 46).

An additional factor aggravating the socioeconomic challenges for higher education has to do with the trend to 'scientification' of employment and work (Teichler, 1996). The service and production industry has become increasingly dependent on the results of research. Additionally, a growing number of positions are labeled as 'knowledge work' and call for high skills and solid academic training. Management positions, especially in large companies with a wide reach, require a university degree (Teichler, 1996).

As many observers of higher education have outlined, major challenges within European universities have occasioned the following changes (Gibbons et al., 1994; Sporn, 1999): diversification of functions, different social profiles of student population, more professional education, diverse funding of higher education, shifting power between academic and administrative roles, focus on efficiency and effectiveness, and new forms of knowledge production. In this realm, science and technology have gained importance by being more tightly linked with each other and with external constituencies. Scientific research has been translated into application-oriented results, thereby raising public credibility and legitimacy. For this amalgamation of science and technology, higher education scholars employ to the widely used term 'technoscience', implying a combination of "basic and applied research, discovery and innovation, science and product, knowledge and commodity" (Slaughter and Leslie, 1997, p. 38).

As outlined earlier, these changes in university science and technology have been based on new economic conditions in many European countries caused by budgetary constraints and new patterns of public spending. Additionally, restructured job markets call for constant relearning of the workforce. These different areas display a general cross-national dynamic and include five major trends: scarce financial resources, changing role of the state, new technologies, continuing education, and increasing globalization (Sporn, 1999).

State budgets for higher education have been restructured in many European countries. Although public funds for higher education are stable or even increasing in some European countries, they cannot respond to the rising number of students. As a consequence, new sources of funding are needed. Public spending is very often based on output measures like the number of graduates or publications. As a consequence, universities have acquired a more diversified public and private funding base and have concentrated their strategies on enhancing efficiency and effectiveness of teaching and research (Clark, 1998; Williams, 1995).

Closely linked to the problem of limited public funds are new mechanisms of coordination and control in higher education systems, especially regarding the role of the state. Many European systems formerly characterized by 'state control' have moved to a state 'supervising' model, with increased institutional self-regulation and autonomy while the state steers the system from a distance. In many cases like Sweden or The Netherlands, leadership structures have been strengthened and quality control is handled through external audits and evaluation (Neave and Van Vught, 1991). As national economies in Europe have become more volatile and dynamic, the life-cycle of knowledge has shortened and employees need to refresh their expertise more frequently. Hence, continuing education and lifelong learning have become key elements of national policies for enhancing economic productivity. Universities responded by expanding their programs, offering adult education, interdisciplinary programs, and part-time studies with a more vocational orientation. This has expanded the number of continuing, postsecondary, and professional education programs. In Europe, this trend has been labeled as the 'professionalization' of general education (Gellert, 1993; Teichler, 1996).

The new knowledge economy is mainly based on the widespread use of technology. Information technology has also changed university teaching, research, and management. The expansion of the Internet and affordable hardware and software have led to computer literacy of large parts of the student population. The impacts on how students learn, professors teach and conduct research, and administrators manage the institution are complex. Recent trends like virtual universities and distance education programs, international research projects, and administrative information systems are a few examples of changes influenced by information technology (Sporn, 1999). Globalization and international competition

have put pressure on colleges and universities. The importance of research and development, the creation of common markets, rising mobility of students and staff, and the free movement of capital have increased the need for universities to contribute to national wealth by making the economy more competitive (Etzkowitz and Leydesdorff, 1997). Consequently, market-oriented university practices and national policies have been pushing for university–industry research and development programs which aim at stimulating regional economic development (Slaughter and Leslie, 1997).

These trends in European higher education systems have caused a process of restructuring of academic science and technology. Developments include new technology transfer strategies, shifting relations between applied and basic research, new funding patterns, and rising need for management capacity within universities.

Consequences for Academic Science and Technology

Knowledge Transfer

Government and universities have been designing strategies which should create and sustain competitive advantage in industry. The critical role of knowledge transfer either through research or through teaching has triggered new alliances between industry, government, and academic institutions. Trends include partnerships between universities and businesses, technology transfer units, incentives for a combination of basic and applied research, and for professors contributing to spin-off or start-up companies (Etzkowitz and Leydesdorff, 1997).

Knowledge transfer is often enhanced through funding for research that supports economic development. At the same time, industry relationships help universities to raise additional funds and support companies in their research and development. In this process, academic science and technology are increasingly linked to form the basis for this relationship. For example in The Netherlands, the University of Twente moved from a third-class technology-oriented institution to a successful university through the creation of new entrepreneurial practices focusing on transfer, research, and development (known as TRD activities) (Clark, 1998).

International organizations like the European Union (EU) have a high interest in knowledge transfer as well. EU projects like EUREKA reflect new state interests by establishing large supranational networks of scientists and practitioners to stimulate technological innovations. EUREKA promotes 'market-driven' collaborative research and development through the use of advanced technologies thereby strengthening European competitiveness.

Problem Orientation

As higher education systems all over Europe have expanded, research and teaching have shifted their emphasis as well. Given the complex requirements of the job market, of knowledge-based industries, and of society at large, research and teaching have to be oriented more to problems than to disciplines. This orientation helps universities to better meet the expectations and needs of external constituencies and offer relevant programs to their students. Increasingly, universities define fields of competence (e.g., environmental economics, social medicine) which combine different disciplines and areas to provide solutions to problems like pollution or AIDS (Gibbons et al., 1994; Dill and Sporn, 1995).

As a consequence, new forms of knowledge production have become necessary. Gibbons et al. (1994) coined the term 'Mode 2' knowledge production, ascribing five basic attributes to it: application context, transdisciplinarity, heterogeneity and organizational diversity, social accountability and reflexivity, and quality control. 'Mode 1' refers to the traditional discipline-oriented research of tenured faculty members. 'Mode 2' knowledge production includes a wider, more temporary, and heterogeneous set of researchers and practitioners collaborating on a problem defined in a specific and localized context (Gibbons et al., 1994).

Market-Based Funding

In Europe, scarce resources for higher education have given rise to new claims for public accountability and performance-based funding of universities. These developments have increased the importance of market mechanisms for financing higher education (Williams, 1995). Departments or groups which work in a field that is highly relevant to industry and society have more opportunities for raising additional funds and for gains in the process of resource allocation. They are also better able to contribute to the university budget through their share of overheads. These additional funds can then be used to cross-subsidize other less 'marketable' areas or programs (Clark, 1998). Mechanisms of market-based funding have also created a more entrepreneurial culture within many European universities. Faculty members responsible for their own research institute or center at universities can form a periphery which obtains additional income and also serves the public need for applied research, teaching, and service (Clark, 1998; Sporn, 1999). Again, fields which can more easily combine science and technology, like telecommunications, are especially inclined to get involved in these activities. Conflicts arise if less successful areas which belong to the tradition of university research and teaching get scrutinized for downsizing or closure (Slaughter and Leslie, 1997).

Managerial Capacity

The new relationship between universities, government, and industry requires institutional management capacity. Given the need to translate external demands into internal responses and strategies, faculty members in Europe – who have been steering universities for decades – have become overburdened. A new type of professional university manager is emerging, who is responsible for institutional efficiency and effectiveness (Gumport and Sporn, 1999). Reforms in many countries like Austria, The Netherlands, Sweden, or Spain were aimed at strengthening the leadership structure of universities.

European universities historically were dominated by strong state control and little decision-making power. But with ongoing reforms in many European countries, professional administrators and university managers have gained importance and governments have delegated many tasks to the institutional level. Consequently, in countries like Norway or

Sweden (Gornitzka et al., 1998) an increase in the number of university administrators can be observed while the size of the faculty stagnates. The rising interest in knowledge transfer based on science and technology is adding to the need for management support for new activities.

Tensions arise from these trends as to the new status of employees and the relationship between basic and applied research. While in many continental European countries university professors have been state employees, new trends call for more flexible and decentralized forms of employment. Also, at the institutional level, basic and applied research will have to be redefined. Although the basic mission of the university includes basic research a more market-oriented system requires a larger amount of applied and problem-oriented research projects.

To summarize, the link between science and technology has played a critical role within universities in Europe. National policies have converged around increasing national economic competitiveness through product and process innovations, channeling students and resources into well-funded curricula that meet the needs of a global marketplace, preparing more students for the workplace at lower costs, and managing institutions more effectively and efficiently (Slaughter and Leslie, 1997).

The expansion of European higher education systems will continue to aim at high participation rates. European economies will need more qualified specialists as well as valid research results in applied fields in order to stay abreast of major technological and scientific developments. Governments will move from a control to a supervising role, thereby trying to enhance new partnerships between higher education and industry to boost the economy. Universities have to emphasize their core commitment to a service function in order to meet these high expectations and needs. Science and technology will continue to play a pivotal role in this development.

Abstract

The American research university's history is inseparable from the growing importance of science and technology to the state in the late nineteenth and twentieth centuries. Successive world wars and ongoing global conflict have firmly connected academic science and technology to government patronage. Even as government support declines, federal policies shape the means through which the research university and its products enter the commercial marketplace.

Introduction

The American research university's history is inseparable from the growing importance of science and technology to the state in the late nineteenth and twentieth centuries. From the passage of the 1862 Morrill Land Grant Act to the establishment of the National Science Foundation in 1950, government and university have established deep and long-lasting connections, although the nature and character of those connections has changed profoundly over time. Once reliant upon private contributions and philanthropic foundations, the archetypical American university, as well as American science and technology, became wards of the state during the twentieth century. By the beginning of the twenty-first century, the American research university was busy recasting its social relations and its position in the nation's institutional and intellectual ecology.

In many respects, this history repeats itself. At the beginning of the twentieth century, a new kind of institution – the private research organization – emerged as a potential threat to the university as the primary site for the production of scientific and technical knowledge. Although such institutions survived, they were incapable of mounting a successful challenge to the university's intellectual hegemony. Research and teaching were powerful resources that other institutions could not match whatever their potential virtues to researchers. Today, universities and government-sponsored research are challenged by private corporations intent on capitalizing upon new discoveries, especially in the biomedical disciplines such as genomics. Ironically, the intellectual property issues that ruled out significant pre-World War II (WWII) government patronage of academic science and technology have returned in a similar guise.

Equally important, the university's internal structure has altered profoundly over the past century, a change perhaps most visible in the shrinking role of university presidents. The presidents of the late nineteenth and early twentieth centuries were dynamic individuals willing to risk reputation and even wealth for their beliefs as they sought to shape and mold institutions. Charles Eliot at Harvard and Daniel Coit Gilman at Johns Hopkins invented the research university in the United States, bringing German ideals to bear in a distinctly American fashion. Later, Harvard University president James Bryant Conant played a critical role in building the atomic bomb and developing postwar national security policy. Conant also led a vigorous public debate over the nature and character of the postwar American state. Presidents in the year 2012 have become largely fund-raisers, anonymous even within their own institutions, let alone – with some exceptions – on the wider stages of national policy.

The American College

The antebellum (i.e., before the American Civil War) American college was an institution devoted to the production of civic leaders, ministers, and school teachers. At heart, it was a character development institution complete with a psychological model of the mind legitimizing its pedagogical routines (Guralnick, 1975; Veysey, 1965). 'Faculty psychology,' the belief that distinct physical areas of the brains were the locations of different emotional and intellectual functions, was the early theory of cerebral localization undergirding the college's character-building program. Whether mandatory Latin or Greek memorization or mathematical reasoning, specific kinds of intellectual work were thought to strengthen the faculties to produce better, more capable citizens. The extent to which science and technology played a role in the antebellum college rested upon their ability to lay claim to this process of disciplining and shaping young minds. Social or economic utility was not yet an acceptable reason for the addition of science and technology to the college curriculum.

Passage of the 1862 Morrill Act granted each state federal land for the establishment of a college dedicated to the mechanic and agricultural arts. These new institutions, including Cornell University, the University of Wisconsin, the University of Illinois, and others became sites for the development of new academic roles and new kinds of knowledge. Because graduate education in the sciences was largely unheard of in the United States, the majority of instructors had studied abroad, mainly in Germany, and to a lesser extent in England and France. The land grant and its equally important sister institution, the agricultural experiment station, were hothouses for the production of a distinctive vision of American science. Utility had been the driving force in the creation of the new institutions, but many of the researchers hired at these new sites desired to transform them into institutions resembling the laboratories of their German teachers, such as the famous chemist Justus Liebig. As Charles Rosenberg (1997 [1976]) argued, the agricultural experiment station yielded the first American hybrid, the scientist entrepreneur. Obtaining resources for research demanded that academics develop techniques and practices capable of

satisfying multiple constituencies, ranging from the local farmer who wanted to know why crops would not grow in area soil, to the dean who wanted researchers to solve problems of interest to potential donors, and the politician who wanted results to justify reelection. Land grant colleges and agricultural experiment stations provided reasons for the support of scientific research so long as such research delivered useful results (Veysey, 1965; Geiger, 1986).

Research

The American research university was the product of two distinct trends – the increasing number of Americans traveling abroad for graduate education and the problems posed by the rapidly industrializing US polity following the Civil War. First, American researchers who studied in Germany came to believe that the German university was the model of a research institution. This was an illusion fostered by the Americans' peculiar status in the German university system – they were as much sophisticated tourists as students and few, if any, pursued the full course of study. American students in German laboratories worked with outstanding teachers, such as Carl Ludwig, but they failed to observe that the German university system trained more professionals – physicians, lawyers, and bureaucrats – than pure academic researchers. When American students returned to the United States to take up academic posts, they brought only part of the German university system back with them (Geiger, 1986; Owens, 1985).

The founding of the Johns Hopkins University in 1876 is often taken as the origin of the American research university. Although President Daniel Coit Gilman promoted the university as a center of *Wissenschaft* in Baltimore, Hopkins represented less Göttingen on the Chesapeake than another form of hybridization: the meshing of research with the antebellum college's character-building function. Gilman benefited from the fact that Johns Hopkins had provided in his will for the foundation of a new university and medical school. However, the meaning of Gilman's innovations – laboratory- and seminar-based instruction – is often lost in the promotion of research. One should see Gilman and the staff he handpicked – including the physicist, Henry Rowland; the chemist, Ira Remsen; the mathematician, J.J. Slyvester; and the biologist, Henry Newell Martin – as men who brought new resources and practices to bear upon old problems. Gilman and other contemporaries such as Harvard University President Charles Eliot believed that post-Civil War America was a nation in crisis, suffering from effects of unprecedented technological change and the breakdown of local social orders in the building of a national culture. Education, that most universal remedy for social ills, was once again called upon to protect and reinvent social order. Research, manifested in the labors of the laboratory and the seminar room, was the perceived antidote for a hyperkinetic market culture. It was in the laboratory, whether working on the cutting of diffraction gratings, as in Rowland's laboratory, or in the seminar room engaged in the philological study of classical texts, that the student would encounter a new form of discipline in which steady and methodical intellectual work would prepare the young mind for the task of living and working in a new social world. More importantly, such students would themselves work as teachers in the nation's colleges and secondary schools, transferring this new form of discipline and understanding to a wider populace (Kargon, 1986; Hannaway, 1976).

In the hands of educational reformers, the laboratory and the seminar room became new technologies for the (re) production of social order. They were also sites of intellectual innovation whose products might have value independent of their pedagogical origins. The *fin de siècle* saw the emergence of two new types of research institutions – the private, philanthropic research institution, such as the Carnegie Institution of Washington (CIW) (now the Carnegie Institution for Science), and the Rockefeller Institution for medical research (now the Rockefeller University), and the industrial research facility, such as those established at General Electric and AT&T. Both institutions sought to break the university's stranglehold on the production of knowledge and each was modestly successful in this ambition. In the new organizations, research had a value for its own sake unknown in the university. Part of the problem was that many American academics were unable to understand why one would want to separate research and teaching. Andrew Carnegie charged his private research facility, the CIW, with the mission of seeking out the 'exceptional man' and providing him with funds and resources to complete his work free of distractions. While the CIW consulted with academics on how to put Andrew Carnegie's generous gift to work, they were hard pressed to keep academics from applying for funds to relieve them of their teaching burden or to pay for graduate research assistants. Neither was an acceptable use of CIW funds. Robert S. Woodward, the CIW's second president, established a variety of research divisions to insulate 'exceptional' men from both the university and other demands on their time (Reingold, 1979).

Industrial research facilities were rather different, and represented a wholesale transfer of the laboratory as a knowledge production site to the factory. Instead of students and theses, the new laboratories produced patents and processes necessary for corporate survival. The high-tech industries of the early twentieth century – electricity and communications – led the way, integrating their corporate structures into the very manufacture of knowledge that might have industrial implications. Despite early press that these laboratories were universities in exile, later studies recognized that industrial research was always basic to corporate needs and goals. Successful laboratories integrated themselves into the firm's business; unsuccessful laboratories fought for independence that quickly evaporated when the firm suffered in the marketplace (Beer, 1958; Reich, 1985; Wise, 1985; Noble, 1977; Dennis, 1987).

The Visible Hand

World War I (WWI) brought about a fundamental reorganization of the university with respect to the production of technical knowledge. Although American academics made no great contributions to the development of weapons technology (save for the peripheral development of intelligence tests Carson, 1993, 2006), they organized themselves in new and powerful ways that allowed for the development of new forms of patronage. In particular, the National Research Council established by Caltech president and astrophysicist George Ellery

Hale, to resuscitate the National Academy of Sciences, proved an invaluable mechanism for the support of university-based research. The early twentieth century had seen the emergence of incredibly wealthy private philanthropic foundations, including the gargantuan Rockefeller Foundation (RF), the Carnegie Corporation of New York, and the Guggenheim Foundation (Kohler, 1991; Kay, 1993). The RF easily dwarfed all its competitors and would forever alter the topography of American higher education. In the wake of WWI, the Foundation supported a postdoctoral fellowship program administered by the National Research Council (NRC). As the historian Robert Kohler (1987) argued, the NRC was a 'trade association' for American science, providing philanthropies with a means of dispensing funds without having to support mundane university needs. That is, the foundations were not interested in supporting undergraduate education, or in building facilities; instead, the RF emphasized a policy of 'making the peaks higher.' Those who had excellent resources and professors became sites where NRC postdoctoral students clustered. In turn, those fellows left for jobs and attempted to build institutions capable of attracting such fellows.

One should note that the RF did not distribute its monies across the disciplines. The biomedical and social sciences were its primary targets of patronage; even during the Great Depression, the RF maintained its funding of these sciences, especially through efforts to import the techniques and instrumentation of the harder sciences into the biomedical and social sciences. It is to an RF officer, Warren Weaver, that one owes the term 'molecular biology,' and the RF's interest in genetics, human biology, and social engineering was to have lasting repercussions in another *fin de siècle*'s most public work, the Human Genome Project (Kohler, 1976; Kay, 1993).

Private support of the sciences was not matched by government support before WWII. Indeed, efforts to have the federal government pay for university-based research ran up against long-standing beliefs that government money invariably brought with it government control. Curiously, American academics did not seem to fear RF funds for analogous reasons. Various efforts to organize federal support of the sciences during the Great Depression foundered on this belief (Kargon and Hodes, 1985; Genuth, 1987; Hart, 1998). Equally important was a fundamental inability of university administrators and government bureaucrats to determine who would own the fruits of government sponsored research (Owens, 1990). Such disagreements made federal support of university-based research nearly impossible, save for research lacking any potential commercial value. Nor was industry a powerful patron of interwar academic science and technology. In large part, corporations sought such tight control over sponsored academic research that researchers almost welcomed the war and the possibility of relatively unconstrained government support (Galison et al., 1992). In postwar America, the state emerged for science as a patron of unprecedented wealth and power.

Wards of the State

WWII's effect upon the American university and American science and technology was profound. American researchers, organized by their leader, Vannevar Bush of Massachusetts Institute of Technology (MIT), and the CIW, instituted a virtual revolution in warfare, bringing about a permanent revolution in munitions, whether it was the atomic bomb or attempts at the mathematization of strategic thinking through operations research. Scholars, especially David Noble (1984), Stuart W. Leslie (1993), and Rebecca Lowen (1997), have begun the task of examining how the war and postwar military patronage transformed specific universities. Others, such as Paul Forman (1987, 1992, 1995), have led an effort to understand how the very content of technical knowledge changed to meet the needs of new patrons. The rise of the military as the dominant patron of American university-based science had far-reaching effects upon the university, not the least of which was a strengthening of the faculty with respect to administrators. It was the faculty with whom military officers established relationships and it was the faculty that produced both the new technologies and the students that the military wanted. In turn, administrators attempted to reassert their authority through the development of new means of accounting, most notably the invention of indirect overhead as a means of capturing revenue from grants and contracts made to specific individuals (Dennis, 1994; Galison, 1997).

Postwar military patronage focused upon four major research areas: guided missiles, continental defense, the managerial sciences, and intelligence related research in areas as diverse as area studies and cryptography. These four domains capture the range of military interest and share a common tool, the digital computer (Edwards, 1996; Ceruzzi, 2003). The development of the ballistic missile brought with it the development of miniature electronic components, including the integrated circuit and the ubiquitous microprocessor. Continental defense, the effort to develop a shield against a possible Soviet aerial attack, produced a range of technologies, including the modem and magnetic core memory. The US continental defense system, semiautomatic ground environment (SAGE), provided corporations like IBM with the technological experience to engage in massive commercial software development, including SABRE, the airline reservation system (Redmond and Smith, 2000). The managerial sciences encompassed a multitude of fields, ranging from the quantitative social sciences, such as operations research and systems analysis, to the emerging field of management science. In turn, interest in the managerial sciences, work that ranged from Simon and Ackoff's views on information processing and management to decision support systems, flourished in the reformed business school of the postwar era (Schlossman et al., 1994; Khurana, 2007). That management might be taught as a science, in the most positivistic sense, was one reason for the growth and development of graduate business education, among the most notable stories of Cold War education. Finally, the effect of the US intelligence services – the CIA and the NSA – remains among the most secret effects of the Cold War on the American university (Simpson, 1998). While it is clear that Area Studies and various departments of communications research were adjuncts to the cold war effort, what remains unclear is the extent to which research on computers, artificial intelligence, and mathematics was driven by the ever increasing needs of national security. The digital computer and its associated academic departments – applied

mathematics, linguistics, computer science, electrical and communications engineering, information theory, etc. – owe much to the nation's cryptographic needs for their development. Given that such work is still considered among the most sensitive, one may never know the depth of the state's penetration into the university.

Markets, Universities, and the State

Even before the Cold War's end, relations between universities and the state began to change. Although national security remained a significant cause for federal research funding, academic science and technology increasingly became viewed as engines of economic growth at both the regional and national levels. Hence, there were an ambitious set of efforts to 'clone' Silicon Valleys or Route 128s across the nation. If Americans were once all Keynesians, they had now become Schumpeterians, believing that the creative destruction provoked by advances in science and technology was the cure for economic stagnation (Berman, 2012; McCraw, 2010; Geiger, 2004). Market logics quickly became the grammar of academic success, especially in the sciences and engineering disciplines. Universities increasingly viewed themselves as incubators for start-up companies in fields as diverse as information technology and biotechnology. Genentech's 1980 initial public offering produced the amount of money that universities had heretofore seen only in federal grants. Blockbusters, long Hollywood's domain, became the next academic frontier as researchers sought to patent and publish, even when the federal government subsidized research. Ironically, few seemed to notice that only a handful of start-ups in any field ever became successful over time.

Even before the 1980 passage of the Bayh-Dole Act allowed universities to patent federally sponsored research, academic institutions had worked with the patent system to raise revenues. During the Great Depression, MIT and other schools had created patent policies to share monies that faculty patents might provide (Metlay, 2006). Although these policies yielded little actual revenues, by 1980 other changes made patents an increasingly viable source of funding. In addition to Bayh-Dole, which removed any questions about university patenting, several other government policies made a big difference. First, the 1978 Revenue Act cut the capital gains tax rate from 49 to 28% and the Department of Labor issued a regulatory clarification allowing pension funds to invest some of their funds in venture capital. Within a few years, there were hundreds of biotech start-ups, as biomedical researchers and venture capitalists looked for a new El Dorado. Second, the 1980 Supreme Court decision *Diamond v. Chakrabarty*, which allowed for the patenting of genetically engineered organisms, greatly expanded what the new start-ups could patent as they attempted to create new markets. Finally, the 1982 creation of a new Court of Appeals for the Federal Circuit, specializing in patent matters, made it clear that the State would work to preserve intellectual property rights. Government policy played a key role in making university-based science and technology marketable (Berman, 2012).

Commercialization had its critics, but the last decade of the twentieth century and the twenty-first century's first decade saw the triumph of a set of beliefs – neoliberalism – arguing that markets and the private sector were the real sources of economic power. Although this view found itself challenged in the wake of the financial collapse of 2008–09 when the Federal government forestalled another Great Depression, the privatization of academic American science and technology continues (Mirowski, 2011). The increasing focus upon STEM – science, technology, engineering, and mathematics – education bodes well for one dimension of the American research university, but an increasing segment of those earning degrees in those fields are foreign nationals who often return to their home country after receiving their degrees. In 2009, the last year for which there are data, 27% of the Masters degrees in the STEM fields went to non-US citizens. Just as US companies have increasingly shifted their physical manufacturing overseas, so have US universities shifted their manufacture of new technical knowledge-producers to foreigners (NSB, 2012). What the future holds remains unclear, but university presidents and faculties will have to negotiate a future in which their work is increasingly viewed as economically vital, but unworthy of massive federal support.

Abstract

In a classic book, *Unobtrusive Measures*, first published in 1966, Eugene Webb, Donald Campbell, Richard Schwartz, and Lee Sechrest made a case for the greater use of data sources *not* dependent on the elicitation of data directly from respondents or informants. They further argued for the importance of combining data obtained using different methods in ways that allowed the methodological weaknesses inherent in particular methods to compensate for one another. The various sources of potential data Webb et al. identified and the justifications they advanced for the use of unobtrusive measures are explored, as is the wider context that surrounded the book's original production. Problems associated with unobtrusive measures, including the ethical issues involved and the difficulty of generating measures relevant to particular research problems are discussed. The relationship of the unobtrusive measures tradition to the wider 'cultural turn' in the social sciences and to new technologies for data capture and collection is outlined.

Introduction

The recognition by social scientists at the beginning of the twentieth century that it was both feasible and desirable to elicit information directly from people about their circumstances, behavior, and subjective states had profound consequences. It opened the way for widespread adoption of survey methods, a variety of interviewing techniques, and the use of questionnaires and self-completion instruments. The difficulty is, of course, that obtaining information from respondents or informants is not unaffected by the interaction between researcher and researched. The act of asking, in other words, shapes the character of the answers given. In a book displaying an irreverent skepticism toward the methodological practices dominant at the time, Eugene Webb, Donald T. Campbell, Richard D. Schwartz, and Lee Sechrest proposed that the "interrogation of experience, attitude and belief" (Kellehear, 1993, 1) might better be accomplished through the use of what they termed 'unobtrusive measures' (Webb et al., 1966); data gathered without a direct interchange between the researcher and the researched. In their view, the great benefit of unobtrusive measures lies in their 'nonreactive' character, thus avoiding threats to data quality caused by the researcher's presence. Accordingly, Webb et al. suggest that social researchers should pay more attention to sources of data such as the physical traces associated with people's passage through their physical environment, observing situations without participating in them, and the use of documentary sources of various kinds. Instead of using interviews and questionnaires, researchers might just as easily answer research questions by watching what people do, by looking at physical evidence of various kinds, or by turning to the words or images inscribed in various media.

Webb et al.'s (1966) book *Unobtrusive Measures* encouraged researchers to seek out novel and innovative ways of using unobtrusive data in research rather than falling back on what had become by the time they were writing standard and predictable ways of collecting data. Arguing that researchers should seek to be imaginative and creative in their thinking about data relevant to particular research problems, *Unobtrusive Measures* offered its readers such intentionally off-beat examples as the use of wear on the floor tiles surrounding a museum exhibit to measure visitor flows; the changing size of suits of armor as a way of measuring changes in human stature over time; and the relationship in the 1960s, at a time when long hair tended to signal political radicalism, between psychologists' hair length and their methodological preferences. However, Webb et al. went beyond simply advocating that researchers should add unobtrusive measures to the methodological repertoire. Their principal objection to traditional data sources is "that they are used alone" (1966, 1). In other words, data collection methods used singly are inferior to the use of multiple methods. Webb et al.'s argument is that any research finding is potentially vulnerable to an assertion that the results found are the product of fallibilities inherent in the data collection process. These fallibilities, however, are not the same across methods. In particular, problems of reactivity do not affect data collected unobtrusively. As a result, configuring different methods, each of which is fallible in a different way, is preferable to overreliance on a single method.

Origins and Contexts

In 1962, the US Office of Education offered Donald Campbell a contract for work on research methods. As he records, part of the final report on the contract was entitled: "Other Measures: A Survey of Unconventional and Cooperation-Free Measures for Social Science" (Campbell, 1988, 19). This report was to provide the basis for Webb et al.'s later book. In its breadth and its emphasis on imagination, creativity, and the use of unusual methods, *Unobtrusive Measures* reflected the circumstances of its production. Individually and collectively, the authors of *Unobtrusive Measures*, all faculty members at Northwestern University, appear to have been both genial and congenial, but their collective production of the book reflected more than conviviality. It was the product of their collective experience and expertise, the breadth of their interests, and the intellectual milieu that surrounded them. The authors of *Unobtrusive Measures*, three psychologists and a sociologist, were scarcely narrowly focused as social scientists. This is particularly so in Campbell's case. Even in his undergraduate days, Campbell

seems to have made a point of being open to a wide and diverse range of intellectual opportunities. His career is notable for the breadth of its engagement with many different scholarly strands within and beyond psychology, intellectual changes of direction, and a penchant for collaboration that included a variety of productive associations with anthropologists and sociologists, including Louis Wirth at Chicago (Campbell, 1988, 10; Shadish and Luellen, 2004). A psychologist by training, Webb's professional background was in journalism (see Webb and Salancik, 1966). Schwartz, the sociologist in the group, worked at the interface between law and sociology (Garth and Sterling, 1998). Both Webb and Schwartz, in other words, worked in fields that relied heavily but skeptically on interviewing, and in which the cross-checking and weighing of sources against one another is important to the assessment of evidence. Since early in his career, Sechrest has also worked across a range of substantive and methodological domains, making contributions to a number of different fields and subspecialisms within psychology (Bootzin and McKnight, 2006).

The book itself grew out of a weekly 'Sack Lunch' at which it became a game to come up with novel methods (Campbell, 1981, 481). (For non-US readers, a 'sack lunch' or 'brown bag lunch' is an informal lunchtime meeting to which one brings one's sandwiches in the eponymous paper sack or bag.) The studied informality of this setting was apparently no accident. Campbell had been at the University of Chicago before coming to Northwestern University. He had found his time at Chicago less than satisfying (Campbell, 1988). Tenure pressures there meant that levels of competition between junior faculty operated in ways, which inhibited the free flow of ideas. In consequence, Shadish and Luellen (2004, 85–86) suggest, Campbell tried to create an intellectual climate at Northwestern University that encouraged open discussion and intellectual diversity, and in which the outlandishness of an idea did not constitute a barrier to its consideration.

One wider, and usually unremarked, context for Webb et al.'s work was the Cold War. The funding of Campbell's original methodological research was made available under the provisions of the National Defense Education Act, which had been enacted as a response to criticisms of the American education system that followed the launch by the Soviet Union of the first artificial satellite, *Sputnik*, in 1957. Some of Campbell's earlier work and further work on the development of nonreactive measures by Sechrest and Phillips (1979) were funded by the Office of Naval Research (ONR). As Solovey (2012) points out, such funding did not necessarily imply that the research had direct utility for the military; ONR, in particular, had something of a reputation for having a hands-off relationship with the researchers it funded. One of the four authors of *Unobtrusive Measures*, Eugene Webb did, however, have a close relationship to the US defense establishment.

From 1967 to 1968, Webb was on leave serving as a staff member at the Institute for Defense Analyses (IDA) (Hastorf et al., 1995), a body mostly funded by contracts from the US Department of Defense that by the mid-1960s had developed an interest in counterinsurgency research (Wakin, 1992). It is not clear how Webb came to take the position with IDA, or how, if at all, his involvement with the organization was related to his authorship of *Unobtrusive Measures*, and the attention the book had attracted on publication. However, one insider account (Deitchman, 1976) records that unobtrusive measures began to be of interest as a component of counterinsurgency studies in Thailand in response to perceived problems with interview-based data collection. Webb went on to undertake a methodological review of social science research in Vietnam critical of how existing studies had been conducted (Rohde, 2011), and to sit on a number of boards and committees looking at utilization of social science research by the US Department of Defense (Klare, 1972; National Research Council Advisory Committee, 1971).

The other authors of *Unobtrusive Measures* do not seem to have taken public positions for or against the Vietnam War. The use during the war of body counts as a supposed measure of combat effectiveness did, though, give rise to what has become known as Campbell's law: "The more any quantitative social indicator is used for social decision-making, the more subject it will be to corruption pressures and the more apt it will be to distort and corrupt the social processes it is intended to monitor" (Campbell, 1979). (The same idea is also expressed in what is popularly known as Goodhart's law, "When a measure becomes a target, it ceases to be a good measure.")

Sources of Unobtrusive Measures

Unobtrusive Measures is organized around a loose typology of data sources: traces, archives, and observation. Traces are the physical residues that social activities leave on the physical environment. Webb et al. distinguish between 'erosion measures' produced through the wearing away of the environment, and 'accretion measures' that reflect the addition of material to the environment typically through abandonment or adornment. Wear on library books as measured by smudges, finger marks, turned-down pages, and the like is a classic erosion measure of a book's use by readers. Accretion measures, Webb et al. suggest, include such things as the amount of litter or graffiti to be found in some setting. 'Garbology,' the application of archaeological techniques to the material discarded in contemporary societies, provides accretion measures important to the understanding of consumption patterns (see, e.g., Rathje and Murphy, 2001). Archives are written records of various kinds. Webb et al. make a somewhat arbitrary distinction between what they call 'running records' and 'episodic records.' Running records are the "ongoing continuing records of a society" (1966, 53), vital registration data, for example, or recurring items in newspapers. Episodic records have a more discontinuous form. In consequence, they do not permit longitudinal research in ways that are possible with running records. When they refer to 'observation' what Webb et al. have in mind are situations in which activity in some setting is recorded without direct interaction between researcher and researched, and, in many cases, without the latter being aware that they are being studied. Observations can be conducted directly by researchers but they can also involve the use of data capture technologies to record activities or interactions as they occur.

Webb et al. pay careful attention to the problematic aspects of using such sources. Thus, traces are ubiquitous, easily

quantifiable, and available at low cost but it can be difficult to make inferences from them. Over time wear on a surface becomes an unreliable measure of use, for example, because the worn area eventually wears faster than it did before. In addition, baseline information that would enable a rate to be calculated from trace data for some measure is often unavailable. Running records reflect the organizational processes by which they are produced (Garfinkel, 1967). The extent to which documents have differentially been retained or survived affects the availability of episodic records, while personal and autobiographical documents might not be free of pressures toward positive self-presentation. Observation can also be problematic. What one would like to observe is not always available to be observed. Nor is the meaning of some observed behavior necessarily obvious without access to other more reactive sources of data. Careful attention needs to be paid to sampling and data recording issues, and to the role and possible impact of the observer on the setting. Serious ethical issues arise in situations where people do not realize they are being observed.

None of the data types described by Webb et al. can be said to be unknown to social scientists. If outside archaeology the analysis of trace data remained relatively uncommon in the mainstream social sciences, the examples of Freud and, from fiction, Sherlock Holmes provide a popular cultural mandate for linking environmental traces to behavioral activity (Ginzburg, 1979). Nonparticipant observation has roots in a tradition going back to the late nineteenth century in which members of the middle class, for reasons of curiosity, adventure, investigation, or reform, went 'undercover' to gain access to and understanding of the lives of the poor or the working class (Pittenger, 2012). In the 1920s and 1930s, the perceived failings of research based on self-report instruments encouraged direct and systematic observation of children at play and in classrooms (Cairns and Cairns, 2006), much of it conducted by female researchers such as the Austrian psychologist Charlotte Bühler, the sociologist Dorothy Swaine Thomas, Mildred Parten, Ruth Addington, and others. Eclipsed, on the one hand, by experimental methods and, on the other, by the rise of self-report methods, the use of documents, personal and otherwise, formed an important strand within a number of social science disciplines in the first half of the twentieth century (Allport, 1942; Gottschalk et al., 1945). Webb et al.'s achievement was to take a residual category, the 'other methods' of Campbell's original study, and animate it with a plausible conceptual frame and a detailed methodological rationale, which they then populated with compelling instantiations.

Triangulation

Although the term does not occur very frequently in *Unobtrusive Measures*, the concept of 'triangulation' is central to Webb et al.'s work. As they put it, "The most persuasive evidence comes through a triangulation of measurement processes. If a proposition can survive the onslaught of a series of imperfect measures, with all their irrelevant error, confidence should be placed in it" (1966, 3). This stance derived largely from Donald Campbell's work. Early on in his career, Campbell had become concerned with difficulties involved in measuring attitudes and establishing the validity of data derived from laboratory experiments. Working with Donald Fiske, he eventually proposed an approach, dubbed 'multiple operationalism,' based around the intertwined notions of 'convergent and discriminant validation' (Campbell and Fiske, 1959). Where different measures for the same trait, construct, or concept converged in the sense of being highly correlated, reliability could be assumed. Where correlations between measures of different traits, constructs, or concepts were low, thus discriminating between them, validity could be assumed.

The term 'triangulation' has its origins in geodetic measurement (Blaikie, 1991; Hewitt, 2010). (It might be relevant here that Donald Campbell had been a naval officer during the war and can be presumed to have been thoroughly familiar with navigational uses of the term.) Campbell and Fiske's work on the multitrait–multimethod matrix had taken a relatively narrow approach that depended on the results of different methods being available in the form of test results, rating scores, and the like. Assessing the effect of 'a series of imperfect measures' therefore involved examining simultaneously and systematically the interrelationships within a (triangular) array of correlation coefficients. This approach has remained strong in psychology. Fifty years on, Campbell and Fiske's work remains widely cited, and a sizable literature now exists devoted to the development, refinement, and extension of their original work (Eid and Nussbeck, 2009).

Popularized by the sociologist Norman Denzin (1970), among others, the notion of triangulation soon took on a wider aspect. In particular, it began to refer in a more general way to the combination of quantitative and qualitative methods. A substantial debate ensued about whether it was possible, desirable, or feasible to combine such methods (for a review, see Bryman, 2006). One position, strongly held, was that particular methods are embedded within wider epistemological and ontological frameworks, which preclude the very possibility that they might be combined. In another view, perhaps more prevalent among those in applied fields and in evaluation research, the case for combining methods was a largely pragmatic one in which epistemological issues, while relevant, were far from determining. In all of this, the notion of 'triangulation' took on a variety of meanings, sometimes referring to the loose configuration of different methods, sometimes to their concomitant use, and sometime to their deployment in an integrated way (Moran-Ellis et al., 2006).

One irony of this debate was that it tended to lose sight of Webb et al.'s specific focus on reactivity. While they are likely to have thought that using survey interviewing and depth interviewing within the same study was better than using either one on its own, Webb et al. would have seen both methods as reactive, even if that reactivity manifested itself in different ways. While the notion of triangulation had opened up the debate about the use of multiple methods, it also paradoxically reproduced a situation of the kind Webb et al. had originally criticized: a reliance on a set of conventional methods, the specific methodological weaknesses of which remained relatively unexamined. Lost, too, was their insistence of being open to the using unexpected or off-beat data sources. From a different perspective, however, what these developments underlined was one of the major criticisms of unobtrusive

measures: the absence of a distinct methodology for generating specific measures relevant to a particular research problem.

Impact, Use, and the Generative Problem

Unobtrusive Measures can with some justification be called a methodological classic. By 1979 the book had sold in excess of 125 000 copies and had gone into its fourteenth printing (Sechrest and Phillips, 1979). It was subsequently published in a revised and expanded edition (Webb et al., 1981) with a new title, *Nonreactive Measures in the Social Sciences*. The original edition was republished in 2000. A number of textbooks aimed, not uncritically, at encouraging students to understand the value of unobtrusive approaches have also appeared (see, e.g., Kellehear, 1993; Lee, 2000; Emmison et al., 2012).

Even quite early on, however, proponents of the approach became concerned about the apparent disparity between the popularity of the book and the extent to which unobtrusive measures were actually used. Webb and Weick in an article on the usefulness of unobtrusive measures in the study of organizations – somewhat pointedly subtitled 'A Reminder' – speak of the 'ceremonial citation' of Webb et al.'s book (1979, 650). Describing the slow take up of unobtrusive measures as "somewhat disappointing and a bit puzzling," Sechrest lamented that while "the idea or concept of unobtrusive measures has clearly caught on, the practice of unobtrusive measurement has not" (1975, 103). Sechrest pointed to a number of reasons for the relatively slow adoption of the innovations proposed in *Unobtrusive Measures*. One was the book itself which he candidly admitted "was little more than a catalog or compendium of disparate techniques of varying degrees of worth" (1975, 103). In addition, the authors of *Unobtrusive Measures* had not attempted to develop further the methodological aspects of the approach in a systematic way. As a result, there was little information about the reliability and validity of possible measures. Perhaps the fundamental problem, though, was the absence of explicit guidance for those seeking to use unobtrusive methods in relation to a particular research problem. Beyond commending particular authors for being 'imaginative' and briefly and jokily invoking Sherlock Holmes as a role model (1966, 35), *Unobtrusive Measures* said little about the topic and provided little explicit guidance to anyone seeking to apply the lessons of the book to their own research.

Eventually, two broad strategies were to emerge to deal with the issue of generating measures relevant to a particular research problem (Lee, 2000). Webb and Weick (1979) detailed a list of strategies by which researchers could orient themselves to problems, methods, or data sources. These include seeking data in unlikely places, using multiple sources of data in multiple ways, being playful and creative, and being alert to patterns and anomalies in particular measures. Sechrest and Phillips proposed a second approach, a generative taxonomy for the identification of unobtrusive measures (1979; see also Webb et al., 1981: Chapter 9). The taxonomy took the form of a matrix with a list of purposes to which measures might be put on one dimension and the characteristics of responses on the other. For example, one might want to assess the degree of interest or involvement in some activity by reference to the frequency with which that interest manifests itself in the activity, or assess affective states through examining how far the choices people make indicate positive or negative evaluations of what has been chosen.

It can be argued that neither of these approaches is entirely satisfactory. The 'orientational' approach adopted by Webb and Weick offers some guidance to researchers but still seems to be too general and inexact to be directly useful. The generative taxonomy proposed by Sechrest and Phillips has the benefit of systematicity. However, it can be seen as being unwieldy (as Sechrest and Phillips themselves admit) and too narrowly focused on particular domains to have much independent generative power. Subsequently, Lee (2000) suggested abandoning both the orientational and taxonomic approaches. He argued instead for developing a variety of heuristics for generating unobtrusive measures. These heuristics were to be based on relevant modes of data acquisition – 'finding,' 'capturing,' and 'retrieving' – understood in an active way rather than on Webb et al.'s passive typology of potential data sources. However, the utility of this approach has yet to be demonstrated.

Ethics

The original edition of *Unobtrusive Measures* makes practically no mention of ethical issues. This was an intentional omission. In the preface to the book, Webb et al. indicated that they disagreed among themselves about the issues involved (1966, v–vi). They also felt that the topic was important enough and complex enough to warrant a separate, extended treatment. A number of reviewers homed in on the book's failure to address itself to ethical concerns. Richard Hill reviewing the book in the *American Sociological Review* notes Webb et al.'s disclaimer but judged it 'not enough' given the increased attention to ethics that was beginning to be seen in the social sciences at the time (1966, 565). In the *Annals of the American Academy of Political and Social Science*, Roy G. Francis complained that, "Except for a disclaimer in the Preface, there is not one damned word about invading privacy, not one hint about the civil rights problems, and no real concern about the fact that social scientists are bent upon studying human beings" (1966, 230).

Webb et al.'s insouciant stance toward ethical issues seems particularly egregious because they devoted an entire chapter of their book to 'contrived observation' and the use of hidden hardware for tracking and monitoring behavior. Contrived observation refers to situations where behavior is observed under induced conditions, such as when a confederate creates a set of circumstances designed to see how those in some particular setting react. Used to study topics such the willingness of bystanders to intervene in emergencies or usually hidden discriminatory practices, such methods rely directly on deception. Standing at the beginning of an era of transistorization, miniaturization, and later digitization that widely enhanced the usefulness and usability of recording devices (Lee, 2004), Webb et al. were clearly intrigued by the possibilities then emerging for logging data from natural settings using hardware of various kinds. The advantage in doing so is that it becomes possible to minimize observer effects produced by inattention, misperception, or fatigue. Deploying hidden cameras and microphones can come to seem, however, uncomfortably like the use of surveillance techniques.

It is perhaps not surprising, then, that the second, revised (1981) edition of the book contained a separate chapter devoted entirely to the ethical implications of using unobtrusive measures. Perhaps raising more questions than they answered, Webb et al. (1981) addressed issues relating to privacy and informed consent. They note that the gathering of trace data and the use of observation often occur in relatively public contexts where expectations of privacy might be attenuated, and point, too, to the practical difficulties of obtaining informed consent in such settings. They also emphasize the responsibility placed on researchers to ensure that research procedures meet ethical standards.

Webb et al. point to the wider role that had been adopted by the U.S. Federal government in relation to the ethical regulation of scientific research, noting that at the time the extension of such regulation to the social sciences was still controversial. Were they writing today it is likely that Webb et al. would note that while the issues they raise have scarcely been resolved in any definitive way, many countries now implement systems of prior ethical review of social science research. The ethical dilemmas surrounding use of unobtrusive measures are no longer, therefore, left to the discretion of individual researchers. Surveying the situation in Canada, especially in relation to unobtrusive studies of discriminatory behavior, Page (2000) has argued that research is increasingly constrained by what he sees as an overrigid implementation of informed consent procedures.

Unobtrusive Measures and the Cultural Turn

Webb et al.'s work predated the 'cultural turn' in the social sciences, the shift beginning in the 1970s that emphasized the understanding and interpretation of culture as a central component of social inquiry. Crucial to the cultural turn was a rejection of measurement, whether unobtrusive or not, as a focal preoccupation of the social sciences. Drawing on a wide range of theoretical and methodological approaches, including postmodernism, semiotics, phenomenology, discourse analysis, and the like, researchers in many disciplines turned instead to interpretive or critical understandings of the social world. Work of this kind would seem to have little in common with traditional conceptions of unobtrusive measures. What these approaches share with Webb et al.'s work, however, is "a rather sideways glance at traditional sources of data in social research" (Lee, 2000, 7). Treating the world as irredeemably cultural opens to study, aspects of social life that in other contexts might be regarded as peripheral, insignificant or taken-for-granted. Much work in cultural studies has been shaped by approaches from literary studies and the humanities that traditionally made little use of elicited data but utilized instead sources historically deprecated or marginalized within mainstream social science. The importance Webb et al. placed on a playful, irreverent stance toward potential sources of data has a degree of resonance with certain kinds of postmodern sensibility.

One starting point for much writing in cultural studies is that the shift toward the use of interviewing and the growth in quantitative techniques that began in the social sciences in the 1920s fostered a sensibility toward data in which the spoken word of the interview was elevated over the textual and the visual. In consequence, the use of personal documents, such as letters, diaries, memoirs, and so on declined (Plummer, 2001), as did the use of photography as a mainstream research method (Stasz, 1979). In recent years, increasing interest in discursive and textual practices, the interpretation of lived experience, and a commitment to overcome the traditional invisibility of disadvantaged, exploited, and colonized groups have all encouraged the revalorization of such sources. Indeed, the new-found popularity of documentary and visual methods and work focused on material culture has produced what is now a very disparate range of work covering a wide variety of substantive topics and methodological approaches.

In the field of visual research, a number of writers have developed integrated frameworks in an attempt to bring some unity to the diversity of approaches (see, e.g., Pauwels, 2010; Emmison, 2010). One benefit of these frameworks is that they allow particular perspectives, including the unobtrusive measurement approach, to be located relative to one another in terms of their assumptions, procedures, products, and the like. Pauwels, for example, has developed a graphical representation that provides a synoptic view of the various pathways potentially linking visual materials of various kinds with relevant research design issues and with the formats and purposes associated with outputs from the research. Within this framework he includes the use of found materials and observational methods of various kinds. The Australian researcher Michael Emmison has developed a framework that begins from the assumption that researchers have tended to conceive of the visual in a relatively narrow way that focuses primarily on objects such as photographs, advertisements, or cartoons. Instead, he suggests a much broader understanding of the visual as that which is "seen and observable" (2010, 236). Emmison in a sense recasts Webb et al.'s preoccupation with the unobtrusive and the ubiquitous by emphasizing how in social life it is often that which is pervasive in the sense of being before our eyes which is routinely invisible. Acknowledging "obvious methodological affinities with an older and these days somewhat neglected and unfashionable – branch of social research, the use of unobtrusive or non-reactive measures" (2010, 243), Emmison goes on to explore ways of understanding what can be seen, whether this takes a two-dimensional form, as in, for example, visual images, a three-dimensional form, as with material objects, or is available to be observed.

Prior (2008) has demarcated a variety of approaches to the study of documents. He points to emerging strands of work concerned with the use and function of documents within particular social settings as opposed to the content of the documents themselves. For the most part, however, Prior contends, documentary research has been preoccupied with content; the dominant approach has been to treat documents as sources of evidence. Even when researchers have obeyed the ethnomethodological injunction to treat documents as 'topic' rather than 'resource' (Zimmerman and Pollner, 1970) they have done so, according to Prior, by examining how content is socially produced. Webb et al.'s discussion of documentary sources stands well within the dominant tradition of documentary research, with its focus firmly on using content as a resource and on traditional concerns with the authenticity, credibility, and representativeness of documents themselves

(Scott, 1990). Having said this, their discussion of the potential for reactivity in documents depends on an implicit, if astute, understanding of how documents are socially produced, and the extent to which the use and function of documents within a setting might index some of its relevant features. (See, for example, Webb and Weick's (1979) discussion of the relationship between organizational constraint and the thickness of procedure manuals.)

Unobtrusive Measures and Technological Change

One area of considerable growth in the period since the emergence of *Unobtrusive Measures* has been telemetrics, the use of wireless information systems for the remote capture and transmission of data relating to physical, spatial, cognitive, and even emotional states. The increasing availability of portable and handheld devices and the convergence of various digital technologies has had a transformative effect on many areas of research concerned with the ongoing flow of activity and behavior (Goodwin et al., 2008).

At the time they were writing Webb et al. could hardly have envisaged the Internet. Its impact on the field of unobtrusive measures has been substantial and significant. Large repositories of records are now readily available online. Social media sites, blogs, wikis, the ratings, rankings, and comments that appear on many Web sites, and online communities devoted to particular topics, all offer boundless research opportunities. It is now often relatively straightforward to combine unobtrusive measures with other sources of online data. For example, one might relate the response to a question on an online survey to the time taken for the question to be answered. One can also note that an ironic consequence of the emergence of online methods is that in the future are they likely to make social scientists less reliant on self-report methods (see, e.g., Savage and Burrows, 2007).

Conclusion

Although their work has its iconoclastic elements, *Unobtrusive Measures* is a gentle book. Webb et al. prefer to make their case through humor, wit, and irreverence rather than through the kind of stridently programmatic writing that was common in many methodological texts in the 1960s and 1970s. Behind its 'oddball' or 'off-beat' facade the book is written in a quietly cajoling style, continually drawing the reader back to the deficiencies of research based on single measures or reactive methods. If Webb et al.'s original rather relaxed take on ethical issues is no longer acceptable, the message of *Unobtrusive Measures* is that everything we do, everything we see, and everything we read is grist to the analytic mill, and that cultivating our methodological sensibilities to recognize the implications of that is no bad thing. Webb et al.'s work also resonates in a period when technological change and the methodological transformations associated with it are increasingly challenging the dominance of self-report methods. The methodological repertoire of the mid-twenty-first century will be far from that challenged by Webb et al. in the mid-twentieth, but its unlikely that their message will have been completely obliterated.

Abstract

Urban anthropology consolidated in the 1970s–80s and became an important section of anthropology and urban studies. It embraces four main fields: (a) urban ethnography to highlight urban conditions and lifestyles, (b) the comparative study of cities as wholes, (c) anthropological studies of urbanization as a process of regional, national, and global social change related to all sorts of problems, especially poverty and slums, urban inequality and ethnicity, and urban environmental and conservation issues, and (d) fieldwork under specific urban conditions.

Introduction

Urban anthropology is a section of general anthropology and urban studies. It embraces urban ethnography and is diversified by regional differences. In short, the subject is quite complex, as it examines various sources of influence and stimuli. The formational phase of urban anthropology took place in the 1960s, a reflection of the contemporary rapid world urbanization especially in Latin America and Asia that occurred after the Second World War. Europe and the United States already had reached high levels of urbanization.

Urban studies demonstrate that the city is one of the most important inventions of mankind. The city is basically an unfolding societal process of increasing interdependency and cooperation of high-density populations in their quest to realize increasingly complex activities by attaining high levels of heterogeneity and specialization (Nas, 1990: p. 35; Karsten in Toelichting, 1938). Cities have paved the way for a cumulative increase in living standards.

Urban anthropology is developing in response to the escalation of almost complete world urbanization, which will be reached in the second half of the twenty-first century when most probably 80% of the world population will be located in urban centers. At this stage, urban studies and urban anthropology will dominate almost the whole society and paradoxically this will mean their termination as a specific subfield in anthropology and other social sciences.

The Formational Stage

After the Second World War, anthropology was dominated by functionalism and structuralism. The attention paid to evolutionist and diffusionist theories had weakened. The study of family and kinship, religion, and hierarchical relationships, based on empirical research by means of fieldwork, was prominent. One obvious indication of this is the book *Tristes Tropiques* by Lévi-Strauss (1955), the founder of structuralism, who relates his travels to some Indian groups in the interior of Brazil. The aims of anthropology were listed by Evans-Pritchard (1963) as the description of important features of societies and cultures, the characterization of the underlying structures and the comparison of cultures all over the world, but outside the West. Participant observation during long fieldwork periods was considered the specific anthropological method, and the principal aim, known as the holistic approach, was to reach an understanding of society and culture as a whole. The well-known introduction to cultural anthropology by Keesing (1958) covers such issues as material culture, social, economic and political patterns, religion, art, and language.

An influential example of a functionalist study on the city in this period is Sjoberg's *The Preindustrial City* (1960). These cities, Sjoberg argues, are rather small with 5000 to 10 000 inhabitants, rarely more than 100 000. They maintain political, administrative, military, economic, religious, and educational functions generally mixed in the city area. Commercial, religious, and administrative activities are situated in the center and professional and ethnic characteristics are bound to specific neighborhoods. The lower class is concentrated in the urban peripheries and the differences between higher, lower, and outcast population groups are indicated by such expressions of cultural differences as language and clothing. Living, working, and religious practices are combined in the same ward. Sjoberg shows that family life was dominated by the extended family, whose functions were many, including procreation, socialization, and social security. Furthermore, these families also played an economic, political, and religious role. The marriages of the children were arranged so that class boundaries were maintained. The roles assigned in marriage were fairly formal, with the women, who were responsible for the upbringing of the children, staying out of the public sphere. The major religious functions that exerted a binding influence were performed by the elite. The political functions were also dominated by the elite who exercise traditional leadership based principally on personal relations and less on strict administrative rules. Sjoberg describes how economic life was dominated by the guilds, which among their other tasks, maintained monopolies and were responsible for the selection and training of members. They also regulated capital and ceremonies.

Although this study by Sjoberg highlights the similarities between preindustrial cities, it disguises the cultural differences between cities in diverse regions. By the 1960s, for example, the specific characteristics of Yoruba, Maya, and medieval cities in Europe had already been highlighted. Krapf-Askari (1969) described the layout of the Yoruba cities (present-day Nigeria) characterized by a palace, plaza, and holy wood

within the city walls. She shows how the different types of family systems, either patrilineal or bilineal, determined the layout of the traditional city and the social and ceremonial integration with the villages, respectively, in a cake wedge and chess board system, as no distinction between city and countryside was made by the inhabitants. This integration of town and countryside also applied to the traditional Maya cities that had a highly ceremonial character (Hardoy, 1973). In contrast, the predominating feature of the medieval city in Europe was a pronounced gap between town and countryside (Pirenne, 1952).

Besides the study of the city as a whole and the comparison of cities embedded in different cultures, the accelerating process of urbanization and its related problems attracted attention. This led to a heavy emphasis on research into two issues, poverty and slums, and to the related matter of rural–urban migration.

In the 1950s and 1960s, Lewis (1959, 1968) published a series of books about his research in the slums of Mexico, Puerto Rico, and New York. He developed the concept of the 'culture of poverty,' implying that a core group in slums, probably all over the world, is not just poor, but has culturally adapted to their poverty, transmitting this subculture from generation to generation. He argues that the specific traits of culture of poverty have been generated by long-term adaptation to a life both marginal and poor, generating distrust toward the institutions in society at large, dependency, and even specific personality traits. His family histories, on which the concept is based, and the descriptions of daily life in slums are an extensive and intricate example of urban ethnography. By this time, urban anthropology was no longer limited to societies outside the West as the Puerto Ricans in New York were one of the groups researched. The study of a black ghetto in Washington, DC, by Hannerz (1969) is another example of the change in focus toward the urban ethnography of poor groups in Western societies. In France the *bidonvilles* of Paris, including that of Noisy-le-Grand mainly populated by French families, were an early field of functionalist slum study focusing on deviant behavior and *exclusion sociale* (Labbens, 1965; Klanfer, 1965).

Migration was the second important subject at the end of the formational phase. By then, the rural exodus and the migration of people from all over the world to Western cities involved ever-growing numbers and could no longer be ignored. The migration model of Lee (1967) distinguished the characteristics of the emigration territory, of the immigration territory, the intervening obstacles such as distance, and the personal characteristics of the migrants such as gender and education. This 'bipole' and push–pull factors model integrated easily into the migration 'laws' that were developed in response to urbanization in Britain in the nineteenth century (Nas, 1974). Anthropologists followed the migrants to the cities in their own countries to discover their motives, their ways of adaptation and subcultures. 'Peasants in cities' became one of the influential titles that betrayed this evolving interest (Mangin, 1970). Later, migration studies also incorporated the growing number of international labor migrants to the Western and Middle Eastern cities in their research. As migrants often, although certainly not always, ended up as poor people in ghettos and slums, migration and slum culture were interrelated to some extent. As main elements in the rapid urbanization process, together they formed the roots of new forms of urbanism.

The formational phase ended in two approaches that are still dominant now and are exemplified by two types of 'introduction to urban anthropology,' one by Fox and the other by Gutkind. Fox (1977) singles out holism, participant observation, and cultural comparison as the main features of anthropology and he shows the different pathways urban anthropology has taken to study urbanism (lifestyle of city people in general), poverty (especially the poor based on life histories), and urbanization (alterations in urban social, associational, ethnic, and other structures in combination with urban problems). His holistic approach has led to the distinguishing of five types of cities: regal-ritual, administrative, mercantile, colonial, and industrial. These categories are discussed in their broader state and administrative settings and elaborately illustrated by case studies. He predicts that the dualism between holistic and microstudies in urban anthropology will be bridged by a focus on the relationships of the different social groups in the city with the larger regional and national social and administrative contexts. Gutkind (1974) has concentrated on African cities, demonstrating their relational, organizational, and institutional complexities in the context of the process of urbanization and the style of life of the inhabitants. He advocates the anthropological study of cities by exploring such concepts as tribalism, ethnicity, pluralism, and modernity, and dedicates considerable thought to rural–urban relations as well as political, work, family, and religious relations and ways of life. He discusses the specific methodological problems of field research in urban areas at length and, acknowledging the need for the application of knowledge, he warns of the false dichotomy between pure and applied studies.

Early Roots

In the 1960s and the 1970s, in attempts to develop urban studies and urban anthropology, urbanists began to search for earlier urban research results and approaches. Sennett's (1969) *Classic Essays on the Culture of Cities* with papers from the German School including Weber, Simmel, and Spengler and the Chicago School with Park, Wirth, and Redfield proved very helpful in deepening theoretical and methodological insights. The contributions of these scholars were widely read by students of urbanism.

Marx, Weber, Redfield, and the works of the Chicago School became especially influential. In 1921, Weber (1958) published his essay on the city in which he compared the medieval city in the Low Countries, the classical ancient cities, the early Renaissance city in Italy, and the Far Eastern cities. He applied his ideal-type method to his analysis and concluded that only the medieval cities in Europe had all the characteristics of the fully developed city, namely, a fortification, market, own juridical system, local political structure, and high level of autonomy. These medieval cities reached the highest level of heterogeneity that Weber claimed was characteristic of the basic role and function of the city. In

their linear evolutionary approach, Marx and Engels (1972, original 1846) were much more negative about the city as they interpreted the gap between town and countryside as an expression of the separation of cerebral and manual labor and one of the dominating forms of alienation. In their contrasting negative and positive views on the role of the city in culture and societal development, the views of Marx and Weber reveal the basic controversy that still characterizes Western culture. The positive attitude toward the countryside is also rooted in the outlook of the traditional European rural nobility, which romanticized country life.

The works of the Chicago School have been interesting not so much for their theoretical approach that uses an ecological analogy but for their urban ethnographic richness. Particularly influential are Wirth's view on urbanism as a way of life (1938) and Burgess' 1925 concentric zone model of Chicago, showing a number of concentric circles with different social and housing characteristics, varying in lifestyle, wealth, and ethnicity. This concentric zone model has been replicated in other cities all over the world, generating a lot of inspiration and new alternative modeling.

The difference between rural and urban was intensively researched by Redfield (1941) who chose a range of communities from traditional folk society to peasant village and city to analyze their characteristics, including worldview, family relations, and cohesion. His work was part of a tradition of community studies initiated by Robert and Helen Lynd in Middletown in the United States (1929) and restudied in 1937. In other countries such as the United Kingdom (Frankenberg, 1966), the community studies approach was espoused. The research on kinship and extended families in cities led Bott (1957) to distinguish close-knit and loose-knit family relations, thereby laying a basis for the network approach. The study of the differences between town and countryside, including those in Western countries, and applying quantitative approaches has attracted many scientists of diverse origins. It led to typologies of cities in various countries and to stereotyping the differences of rural and urban areas and later it has shown that many cities are home to traditional types of communities and some small rural communities can display a rather urban type of outlook.

The Chicago School combined the overview of different settlements in Mexico with elaborate research on areas, communities, and situations in Chicago. They covered a wide variety ranging from the ghetto and slum to the Gold Coast and from the hobo bohemians and gangs to the dancing immigrants in the taxi-dance hall. These studies have continued to captivate and stimulate urban anthropologists and have laid foundation for an abundance of studies of urban components, such as wards, communities, professions, meeting places, and events all over the world.

Two other sources of inspiration have been the Copperbelt and Java studies. Hannerz (1980) presents an overview of the early research in the Copperbelt, Zambia (Africa), by the Rhodes-Livingstone Institute with authors such as Wilson, Gluckman, Southall, Epstein, and Mitchell. Their work analyzed adaptations to life in the towns and raised the matter of whether an African townsman with his intensive tribal and rural relations remained tribesman or not. The conclusion was that a townsman was a townsman and that tribalism in towns was an entirely urban phenomenon. The migrant was detribalized in the city and deurbanized when he returned to the village. Particularly interesting are the situational analyses and the extended case study methods as developed in the Copperbelt studies. Gluckman (1940) takes the opening of a bridge as point of departure to obtain insights into the various persons and groups that take part in the ceremony and describes their relationships to explain the colonial conditions, *la situation coloniale* (Balandier, 1951). Mitchell (1956) also took a specific event, namely, the Kalela dance and the roles performed by the medical doctor, the nurse, and so on to shed light on tribal and colonial relations.

In the colonial period, the Java studies of cities were written in Dutch, often by scholars who had been trained as colonial administrators or were educated in Dutch universities in language and law of the Netherlands East Indies or architecture. They were extremely interested in the architecture, cultures, and languages of the Indonesian Archipelago and wrote extensively about what they encountered in their places of residence. Only in 1958 under the title *The Indonesian Town* (Wertheim et al., 1958) was part of their work published in translation. Town development in the Netherlands Indies, including traditional town formation, the analysis of the urbanization process and its accompanying problems, the layout of a regency town, the living conditions of the coolies and the administrative alterations in a small town were issues discussed at length. Many works from this colonial period have never been translated, including those of Tillema and Karsten, not to mention the masterpiece of de Haan (1922) on Old Batavia that was amply used in her PhD dissertation by Milone (1966). To abstract the specific features of colonial society in the Netherlands Indies composed of a Western and native section, the concepts of bazaar economy, dual economy, and plural society were defined. Later, these were elaborated by other concepts like the informal sector. All the studies on the Javanese and Copperbelt towns have greatly broadened the scope of urban anthropology and strengthened its consolidation in the 1970s and 1980s.

Consolidation

In the 1970s and 1980s, urban anthropology was still young, but its consolidation on the basis of the growing number of research works undertaken in cities, the increasing migration streams to Western cities leading to integration problems, and the rapid urbanization in cities outside Europe and the United States strikingly resulting in overwhelming slum areas and conspicuous poverty was imminent. Its three main pillars were (a) urban ethnography to highlight urban lifestyles and urbanism as city culture, (b) the comparative study of cities as wholes in various societies, and (c) anthropological studies of urbanization as a process of regional and global social change related to all sorts of problems, especially poverty and environmental issues.

At the end of the 1960s and the beginning of the 1970s, the general feeling in Western society and social science was fundamentally changed by the revolutionary quest for new societal forms distinct from the 'conservative' post-Second

World War reconstruction mentality. In urban anthropology, center–periphery and dependency theories were used to explain dependent urbanization in Latin America (Frank, 1967), Africa, and Asia. Galtung's (1971) model emphasizing a center and a periphery in both central and peripheral countries was intricate and shed considerable light on the dependency relations between cities in the world and the differences between Western and Southern urbanization processes. It was used for the interpretation of city size distributions in the world and the explanation of internal and international migration patterns (Nas, 1974).

La question urbaine by Castells (1972), presenting an elaborate Marxist approach to the city, was particularly revealing. Castells rejected the culturalist and harmonic approach to the city that explained urban culture as the consequence of simple demographic density and social complexity factors intensified by rural–urban migration and rapid urbanization. He was convinced that city culture should be explained by the social structure of the society as a whole and, particularly, the historical formation of the capitalist class structure and imperialism. Consequently, the cities in the First, Second, and Third World are completely different in character as they have been produced by capitalist industrialization in the West; imperialist, industrial, and financial domination in the Third World; and the socialist mode of production in the socialist countries. The Third World city consists of a concentration in large agglomerations tending to lack integration into a hierarchical urban network, with a great distance between large settlements and the countryside, an ecological juxtaposition of the autochthonous and Western city wards, a legacy of the colonial period, and a production system set up to serve the dominant Western societies. Hence, slums are not marginal or disintegrated as they often display an important degree of social cohesion. What characterizes inhabitants of slums is that they have interests different from those of the dominant class in society. In contrast to Third World urbanization, socialist urbanization is characterized by the primacy of politics, while First World urbanization displays large metropoles and megalopoles with a wide distribution of activities, functions, and groups, plus the disappearance of the difference between town and countryside. At the end of the 1980s, after the fall of the Berlin Wall and new economic policies in China, the Marxist approach was more or less abandoned. What did remain, however, was the view of the city as an arena in which various interest groups try to realize their ideas or their 'urban meanings' about the development of the city. A focus on urban protest movements in the urban arena was related to this (Castells, 1983). When one or other interest group has formed an elaborate vision for the future development of a city and is backed by the resources to realize its plans, it is called a strategic group (Evers and Schiel, 1988). Urban arena and urban meaning are still pivotal concepts in urban anthropology.

Later, the urbanization branch of urban anthropology was continued, for instance, in the work of Southall (1998), who focuses on the crisis in the capitalist mode of production where it is being affected by all sorts of environmental and social problems such as climate change, heightened risk of flooding, pollution, and other ecological disasters. Besides giving an analysis of the pristine, ancient, and feudal city, Southall discusses the Asian, Third World, and Western cities. His volume, which has apocalyptic overtones, is fairly comprehensive.

Meanwhile, besides their slums, both the informal sector of the cities of the Third World was widely investigated in an attempt to determine possible chances of development as well as urban ethnic minority problems arising from the influx of migrants from Third World countries to Western cities where these groups formed what became known as the Fourth World. These studies were of an applied nature and their purpose was to solve concrete problems. This drive to obtain research results in the expectation of defining and 'solving' problems provided a strong impetus to the consolidation of urban anthropology.

In 1979, the Society for Urban Anthropology was founded as a subdivision of the American Anthropological Association and in 1983 the International Union of Ethnological and Anthropological Sciences installed the Commission on Urban Anthropology (Nas and de Groot, 2009).

By now, urban anthropology was generally accepted as an important part of general anthropology and this implied that anthropology had turned its attention to both applied studies and to Western urban societies. These applied studies concentrated principally on slums, low-cost housing and *kampong* improvement, the informal sector, and urban ethnic minority studies tended to serve as a backup for urban policy and planning. Urban anthropology proliferated with an abundance of research on cities and urbanization in various countries on different continents, often published in collections of articles. It was also influenced by scholars from other disciplines as among them Lynch (1960), Turner (1976), and Kostov (1991) from architecture and Mumford (1961) and Braudel (1987) from history, and by a multitude of sociological studies (Hatt and Reiss, 1951; Ward, 1976), geography (Hauser and Schnore, 1965; Santos, 1971), and urban planning (Epstein, 1973; Friedmann, 1973).

Urban ethnography also steadily continued to broaden its boundaries by including all sorts of lifestyles and professions present in the urban arena, investigating specific ethnic and age groups, scavengers, construction workers, *becak* or pedicab drivers, prostitutes, and small middlemen and traders.

This proliferation of urbanization and ethnographic studies eclipsed the comparison of cities as wholes. Earlier Redfield and Singer (1954) had distinguished between orthogenetic and heterogenetic cities, the former being characterized by the continuation of traditional high culture and the latter by the integration of influences from other cultures. Hannerz (1980) differentiated Coke, Commerce, and Court towns and proposed an analytical model based on roles and role inventories to compare cities as wholes. In geography and sociology, the comparison of cities developed empirically and quantitatively, using large numbers of variables analyzed by factor analytical techniques.

Urban anthropology also made progress in theoretical approaches to urban societies, for example, by applying network theory to survey the city as a network of networks (Hannerz, 1980) and the dramaturgical perspective of Goffman (1959), who approaches institutions in urban society as if they had a front and a back stage on which persons present themselves in different ways.

Examples of important urban anthropological collections of articles that have broadened the horizon to different continents and subjects are the first publications of the aforementioned Commission on Urban Anthropology under the title *Town-Talk: The Dynamics of Urban Anthropology* (Ansari and Nas, 1983), with examples from the Gulf States, West Africa, Japan, and Venezuela, and *City and Society* (Southall et al., 1985) with Bulgarian, African, Kuwaiti, and Indian examples and studies on lifestyles, ethnic groups, middlemen in the grain trade, and workers in the supermarket industry. Other contributions with regional scope deal with Mediterranean (Kenny and Kertzer, 1983), African (Peil and Sada, 1984), and Indonesian cities (Nas, 1986) to mention just a few. Many publications broadening the scope of urban anthropology have followed, often with the words 'Third World cities' or 'cities in developing countries' in the title (Breese, 1972).

As mentioned earlier, in the 1970s and 1980s, slums and low-cost housing, the informal sector, and ethnicity were the hot topics. The thinking about slums in urban anthropology was heavily influenced by the architect John Turner (1978). He took exception to the idea that slums are cancers in the urban constellation and must be eradicated by destruction, relocation, and the introduction of massive low-cost housing projects by the government. Turner realized that new, low-cost housing was often too expensive for the inhabitants of the slums and argued for a decentralist approach in which planning and construction decisions were made by the users. He also stressed that slums represented enormous investments to their inhabitants, value that should not be ignored but appreciated. Turner reversed the negative attitude toward slums, turning it in a basically positive direction and pointed out that the needs of slum people are diverse, varying from location near work and low costs in the first phase of settlement in the city to housing security, only moving on to services in a later phase. These needs were related to the migration pattern in the city. *Le droit à la ville*, the right to the city, of the citizens was also stressed by Lefebvre (1968).

In the 1970s, the concept of 'informal sector' was very influential in urban anthropology. The idea was that, in developing countries especially, there were major informal activities that were not regulated, not counted in the statistics and hence remained outside the official administrative system. Among other factors, these activities dealt with small amounts of goods, services, and capital, thereby involving the application of traditional techniques, and they were often family based. In the formal sector, such activities would have required large amounts of goods and capital, and they would have been officially registered and based on contractual relationships. This distinction generated a flood of anthropological research in attempts to describe the informal sector and its development potentials. In the course of time, it became clear that the distinction was not as clear cut as had been expected. Members of one family could work in the formal and informal sectors and persons could even be involved in both sectors simultaneously. Some activities were shifted from one sector to another as it could be profitable not to be registered in the formal sector for tax avoidance purposes, even though this might imply less security. The conclusion was that perhaps the concepts of informalization and formalization would be better research tools. In explorations of development, expectations of the informal sector were raised high and many projects initiated. Hernando de Soto (1989) who gave examples from housing and transport generated particular optimism in the development of Peru by proposing to eliminate all sorts of official bureaucratic obstacles to entrepreneurship in the informal sector. The results turned out to be less than convincing, although the importance of entrepreneurship in development is widely recognized nowadays. The informal sector approach generated a wealth of research on all sorts of urban activities, including street-sweepers, scavenger communities, street children, small itinerant traders, construction workers, and persons operating traditional means of transport.

Alongside slums and the informal sector, urban ethnicity emerged at this phase of consolidation. It concerns people who share a system of norms and values and have to interact with other population groups in 'complex societies,' as cities tend to be increasingly labeled (Cohen, 1974). Hence, urban ethnicity is a very general concept, rightly ignoring the almost racial connotations it might have. Cohen (1974) shows the possible interrelationship of urban ethnicity with social inequality and political power. When class and ethnicity coincide, they could reinforce each other, and political power could be acquired on the basis of ethnic connections. Some of the examples of ethnic groups in Cohen's book are the Hausa in Nigeria, the Protestant and Roman Catholic groups in Northern Ireland, and the economic elite dominating the city of London. However, many other countries also provide examples of this type of group, for instance, the Pakistanis in the United Kingdom, the Chinese in Indonesia, and the Moroccans in the Netherlands. When migrants settle in a society, as time passes, their adaptation process can lead to integration or assimilation, but this often produces problems in the larger society. Importantly, all sorts of other modes of connection of ethnic groups with the receiving society are possible and are found in history. As seen earlier, in Africa urban ethnicity was discussed in terms of tribalism and in Latin America regional clubs have been important (Jongkind, 1974). Initially, these clubs were considered as a vehicle of security and adaptation; later it emerged that the leaders and members of regional clubs were already successful in the city and did not need them for upward social mobility.

To round off this phase on the basis of two introductions in urban anthropology (Eames and Goode, 1977; Press and Smith, 1980), one can list the following main issues: (a) types of cities and their roles, (b) urbanism and the process of urban change, (c) urban differentiation (gender, social class and ethnic groups, urban sites and places, and professions in cities), (c) urban integration (families, associations, networks, situations, and meetings), and (e) methods of research.

Current Developments

The last two decades have been shaped by various fundamental developments. These have directed the urbanization branch of urban anthropology away from its focus on complex societies to the even more complex global network society. The fall of the Berlin Wall has created new political conditions that unite the world in many aspects and the distribution of new

telephone and Internet facilities has transformed the whole world providing easier direct long-distance connections that have transformed the world financial system, international business, market relations, and local and regional identities. Generally speaking, this has become an intense process in both globalization and localization. In a three-volume masterpiece, Castells (1996–98) has described and analyzed these current processes and their impact on the city. He distinguishes the 'space of places' and the 'space of flows' in megacities all over the world, referring, respectively, to a local and historical community part of a city and a global, ahistorical part linked to the global flow of ideas, money, and so on. Both have their own ways of life, even architecture, featuring the local, more traditional constructions on the one hand and the global, starkly, and modern architecture on the other hand.

Different regional urban experiences were combined by Gugler (1996) into one volume listing Monsoon Asia, China, India, Indonesia, the Arab world, Africa South of the Sahara, and Latin America in an attempt to describe convergences and divergences in urbanization. In this branch of urban anthropology, the different sciences have been almost completely integrated. Hence, environmental aspects have been added to these studies by dint of focusing on certain relevant areas in the city and the purpose is often applied research. Other examples of regional specification deal with Japanese cities (Karan and Stapleton, 1997) and Caribbean cities (Jaffe, 2008).

In the ethnographic branch of urban anthropology, more and more parts of cities are being covered, including particular buildings, the mall, the square, plaza or *alun-alun*, the street, the neighborhood, urban greenery, water problems, graveyards, and urban agricultural and architectural conservation areas.

Data are also being acquired about different ethnic and social groups in cities as well as about social and economic activities. The employment of and changes in the use of mobile phones and the Internet and participation in Internet communities is especially interesting. There is an increasing tendency to frame ethnicity as multiculturalism. Guliana Prato (2009) raises the question to what degree multiculturalism is compatible with citizenship. She points out that the receiving society is not static and does not consist of one single culture, while the immigrant cultures often are also composed of many cultures and are being altered because of their connections with the larger societal settings (Harris, 2011). The number of studies on women in urban areas, investigating their entrepreneurship, is growing, which means that gender studies are increasingly integrated into urban anthropology (Jarvis et al., 2009).

The four volumes of the *Encyclopedia of Urban Cultures: Cities and Cultures around the World* (Ember and Ember, 2002) form an inclusive inventory of data on a great number of cities in the world, providing general urbanization and ethnographic information.

In the branch of urban anthropology directed toward comparing cities as a whole, a new approach has evolved under the label 'urban symbolism' (Nas, 1993; Nas and Samuels, 2006). In this approach, the means of existence is not the point of departure in the characterization and comparison of cities, but has to cede precedence to the symbolic and ritual dimensions that reflects other aspects such as the work relationships. A multitude of cities have been studied in this framework and this has led to new concepts for the study of cities as a whole inspired by the Chicago School spatial models, semiotic signification ideas, and social cohesion studies. Cities seem to abound in symbols (Nas, 2011) that can be used to characterize them and to describe their soul. Urban symbolism studies can be used as a tool in city branding and marketing. This urban symbolism approach corresponds to the insights of Lefebvre (1974) into the production of space, that distinguishes natural space, the perception of space, and the representation of space; Harvey (1990) on time and space; and the work of Nora (1984–92) and his realms of memory. In the framework of urban symbolism, Dürr (2005) has published a case study of Albuquerque in the United States and Till (2005) of Berlin in Germany. Shahshahani (1998) has analyzed Esfahan in Iran and Colombijn (1998) Canberra in Australia to mention a few examples.

One can conclude that in current urban anthropology studies, many old themes are being continued in new ways. Migration has been transformed into international mobility by a network approach and takes place in transnational spaces (Smart, 1999), urban ethnicity as a further phase beyond multiculturalism (Prato, 2009), and the urban way of life with solitude alongside solidarity and loneliness (Coleman, 2009). Interesting new developments cover many topics such as gated communities (Low, 2003), the influence of mobile phones and the Internet (Postill, 2008), wounded cities (Schneider and Susser, 2003), urban heritage conservation (Brumann, 2009), traditional and colonial architecture (Schefold et al., 2003–08; Nas, 2006), and a host of books and essays about urban agriculture and farming, low-density agrarian-based urbanism (labeled *kotadesasasi*), urban soundscapes, the city at night, environmental activism, besides all sorts of urban localities and communities, among them neighborhoods, an urban skateboarding community, and a boxing gym.

Many of these themes refer to worldwide processes. In 1998, the prevailing view on globalization prompted the Society for Urban Anthropology in the United States to change its name to the Society for Urban, National, and Transnational Anthropology. In 1983, the cooperation between urban anthropologists and representatives of other sciences led to the setting up of an Urban Laboratory (as part of National Center for Scientific Research (CNRS)) in Paris. Jacques Gutwirth and Colette Pétonnet (1987) played an important role in the foundation of this *Laboratoire d'Urbanisme*.

Urban anthropology has passed through a great number of theoretical-, concept-, or reality-driven approaches. These have covered the urban ecology analogy, functionalism, network analysis, the dramaturgical perspective, migration models, culture of poverty research, community studies, situational analysis, the extended case study approach, ideal-type comparison, Marxist approaches, structural imperialism, informal sector research, social inequality research, urban symbolism, transnational research, and so on. The anthropological study of the city has proved flexible and able to absorb the developments in general anthropology and other related sciences as well as the outside urban realities that shape our world.

Fieldwork

Field research in cities and megacities differs from the traditional fieldwork in rural and tribal areas as the researcher is generally part of a multimillion population and often known to a limited number of people in the city. The globalization of society has created new possibilities for frequent short visits to the research area. Once long fieldwork visits of one or several years dominated and were preferred, whereas nowadays a series of shorter visits to the same area are possible, even necessary because of the publish-or-perish pressures in the academic world. It has also become possible to study multiple locations, for example, in the case of migration both the area of departure and the receiving area. Marcus (1995), Hannerz (2003), and Falzon (2009) have elaborated on this relatively new fieldwork tendency called multisited or multilocal ethnography, and contrasted it to the 'fly-on-the-wall perspective' (Katz, 2010: p. 26). Under the motto of "follow people, connections, associations, and relationships across space (because they are substantially continuous but spatially non-continuous)" (Falzon, 2009: pp. 1–2), now it is even possible to investigate certain research objects in different locations and describe their fate in various communities. An interesting example of 'follow the thing' is Greek whisky (Bampilis, 2010). In urban anthropology, besides one-location fieldwork in a specific neighborhood or on a specific square, multisited fieldwork is quite common, as when symbols and rituals are 'followed.' In a nutshell, under the influence of globalization, present-day fieldwork tendencies cover a much wider sequence of locations rather than being concentrated in the area of one city or agglomeration.

To illustrate the specific character of urban fieldwork, the concept of the *flâneur* might be instructive. In contrast to research in small urban communities where everybody is soon aware of the stranger in the community, in the city as a whole, particularly in megacities, the anthropologist is immersed in a crowd of people and a multitude of places. His first task is to familiarize himself with different places: their uses, functions, and the people who frequent them. This exercise transforms the anthropologist into a *flâneur*: a stroller, a wanderer, who has no specific relationship with the places he or she is interested in and is eager to make contact with everyone who happen to cross his path in his quest to discover what the inhabitants do and think. The *flâneur* is an observer and a participant collecting general knowledge about the city. This task is the starting point for developing a view founded on his personal background, including the relevant literature, but can later blossom into an intimate knowledge of the views expressed by certain categories and groups of inhabitants, especially those of the key informants who play a prominent role in the research. Besides being an observer and participant, the *flâneur* is also a detective because his ultimate goal is to combine all he has learned into one narrative that will unite the fragmented views held by the inhabitants in one, single model and thereby expose the soul of the city, its structure, and dynamics.

Charles Baudelaire, who introduced the concept of *flâneur* in 1863, wrote the following: "For the perfect *flâneur*, for the passionate spectator, it is an immense joy to set up house in the heart of the multitude, amid the ebb and flow of movement, in the midst of the fugitive and the infinite. To be away from home and yet to feel oneself everywhere at home; to see the world, to be at the centre of the world, and yet to remain hidden from the world …" (Baudelaire, 1995: p. 9). The flâneur is "the painter of the passing moment and of all the suggestions of eternity that it contains" (Baudelaire, 1995: p. 5). "He marvels at the eternal beauty and the amazing harmony of life in the capital cities … He gazes upon the landscapes of the great city …" (Baudelaire, 1995: pp. 11). The message conveyed by Baudelaire is that the *flâneur* is a member of the crowd and a connoisseur of urban life; he is an active, intellectual observer driven by curiosity and he combines the casual eye of the stroller with the purposeful gaze of the detective.

The true home of the *flâneur* was nineteenth-century Paris whose arcades provided his principal domain (Hazel Hahn, 2006); the city was his interior, his house. That is why sometimes, in the guise of a public type, the *flâneur* is restricted to nineteenth-century Paris in the scientific literature. He is considered to have disappeared when the shopping arcades were superseded by large department stores exuding a full-fledged consumer ideology, and when the interior of those shops became the exterior of the city and the domain of the consumer public.

Walter Benjamin (1991: p. 524) elaborates the contrast between the *flâneur* and the traveler or tourist. The tourist restricts his attention to the monumental and places of special interest, 'the exotic and picturesque' as it were (Goebel, 1998: p. 379), and is not actually involved in either urban history or city life. The *flâneur* tries to incorporate the native view, as he is interested in the background and history of the urban landscape and society. *Flânerie* emerges from the confrontation between the city and the biographical background of the *flâneur*, or the 'dialectical movement of familiarity and strangeness' (Goebel, 1998: p. 379). In this dialectical movement, the *flâneur* is also a detective. It suits him to hold himself apparently inert among the urban masses, but in reality he is a passionate observer and participant (Benjamin, 1991: p. 554), eager to understand the city and, like a journalist, takes notes on urban life. *Flânerie* is 'an activity of ethnographic exploration' (Goebel, 1998: p. 389).

In the course of time, the theory on the *flâneur* and *flânerie* has given rise to specific methods of enjoying and exploring the city. Schulte Nordholt (2008) discusses these in her examination of Georges Perec and his sociology of daily life. The immobile *flâneur* might choose to take up his post in a particular café or some other location and sit there to observe what is happening in the street. The mobile *flâneur* can follow one person during the day and write down what the person observed has been doing, perhaps visiting shops, talking with friends, and so forth. He can also take up his position three times a day at different spots in a particular square and describe what happens from different angles. Alternatively, he can observe the same place for one day over a period of several years. An even more common method is just to roam the city at random happening upon the unknown places and vistas, becoming acquainted with the architecture and plazas, relishing accidental encounters, and festivities. Nowadays, urbanists and architects still opt for this way of exploring the city.

Another possible step could be to include an imaginary exploration of the city by drawing mental maps or even by

narrative mapping without setting a map down on paper. In present-day research on urban symbolism, mental and narrative mapping play an essential role as they form a rich source of insight into the city as it has been expressed by informants.

As *flâneur,* the aim of the urban anthropologist is to achieve a synthetic approach to the order and dynamics of a city, repeatedly using observation, participation, interviewing, and reflection. This is a creative and iterative process repeated until an optimal insight has been achieved. The *flâneur* is the symbol of the anthropologist mastering the city. The *flâneur* is an urban anthropologist *avant la lettre* and the urban anthropologist is a modern *flâneur*.

Urban Conflicts

Liam O'Dowd, Queen's University, Belfast, UK

Abstract

Three sources of urban conflicts are identified: (1) changing state–city relationships; (2) the relationship between the dynamics of capitalist development and cities; and (3) the specific dynamics of urban life and the urban environment where the city itself is seen as a causal variable. Two sets of questions crosscut all three strands. The first addresses how violent conflicts can be regulated, transformed, and rendered into more constructive nonviolent conflicts through the processes of urban civil society. The second concerns how, why, and where urban conflicts turn violent and with what consequences. In summary, cities now rival states as arenas and stakes in political conflict and urban conflicts have an increasing transnational and transcultural salience, which underlines the necessity for more sustained comparative analysis.

Three Research Frameworks: An Introduction

Urban conflicts have been framed and constituted historically by the making and unmaking of states, by changing patterns of economic development and by the specific effects of densely settled populations living in close proximity. As objects of research, they vary enormously across time and space, in terms of their causes, outcomes and the forms they assume. In order to make sense of a highly diverse and unwieldy research field, it is useful to identify three underlying frameworks of analysis, each of which sees urban conflicts as shaped by a different process or dynamic. These include (1) changing state–city relationships; (2) the dynamics of global capitalism; and (3) the specific dynamics of urban life and the urban environment. While these approaches may be distinguished in terms of what they choose to emphasize, in practice, i.e., in any one study, these processes may be frequently conceived as overlapping, intertwining or interpenetrating.

Violent and Nonviolent Urban Conflicts

Implicitly at least, social scientific debates on all three processes distinguish between violent and nonviolent urban conflicts. In practice, however, the research and policy literature has been increasingly drawn to questions of urban violence, its causes, consequences, multiple forms, and how it might be defined, regulated, or transformed. Research on urban violence needs to be contextualized within a much wider social science tradition on the multiple origins, definitions, manifestations, and consequences of violence generally and the various ways in which it may be studied empirically (see Heitmeyer and Hagan, 2003). Understanding the scale, diverse manifestations, and variability of urban violence has become the touchstone of much research on urban conflicts. Muggah (2012), for example, provides a detailed overview of the global literature on urban violence and includes an annex, which lists the most prominent research networks and Internet resources on the topic (see also, World Bank, 2010; Agostini et al., 2010). At times, the problematizing of urban violence tends to obscure the fact that conflict per se is the *sine qua non* of urban life and that much of this conflict remains nonviolent, constructive, and agonistic rather than violent, destructive, and antagonistic.

Cities generally have a long history of managing nonviolent conflict and in creating institutions that regulate agonistic conflict. Cities' association with the development of civil society is a recurring theme linking them to a capacity to 'politicize' or moderate conflicts among key violence-prone groups (Varshney, 2002; Keane, 2006). In his History of Violence, for example, Muchembled (2012) accords European towns of the Late Middle Ages, a precocious status in the 'civilizing process'. He suggests that, through a form of 'municipalization of violence', they regulated and pacified those prone to disorder and violence such as young males, prostitutes, and criminals. Young males, however, continue to be seen as a problematic category, i.e., as perpetrators and victims of urban violence, both transhistorically and transculturally (Muggah, 2012: 48). Nevertheless, there is huge variability in rates of urban homicide, with dramatically declining rates in Europe over the past four centuries Muchembled (2012) and currently high rates in some Latin American and sub-Saharan cities (Muggah, 2012: 47–50).

There is no unambiguous connection between cities and forms of conflict. On the one hand, cities can represent protection, safety, resilience, dense networks of reciprocity, economic productivity, and functioning welfare systems (formal and informal). On the other hand, they may be sites of extreme forms of violence, war, insecurity, inequality, poverty, and fear (Muggah, 2012: 2).

In sum, much contemporary research on urban conflicts, across all three frameworks identified above, revolves around two sets of questions. The first addresses how violent urban conflicts can be regulated, transformed, and rendered into more constructive nonviolent conflicts through the processes of civil society. The second concerns how, why, and where conflicts turn violent and with what consequences? Agostini et al. (http://www.eisf.eu/resources/item/?d=41760), for example, seek to develop an analytical framework for understanding the processes of economic, political, and social violence by focusing on the interaction between risk factors in three cities: Nairobi, Kinshasa, and Bogota. The Urban Tipping Point research project led by Moser and Rodgers, studies four cities, Nairobi, Dili, Patna, and Santiago/Chile, in an attempt to understand how the conflicts in inherent in urban life (associated with poverty, youth, political exclusion, and gender-based insecurity) can tip

over into generalized urban violence (http://urbantippingpoint.org). Violent urban conflicts are highly heterogeneous, multicausal, spatially uneven, and typically episodic. Moreover, they also generate long-term urban effects enhancing spatial segregation, discrimination, strengthening ethnic, class, gender, racial, and intergenerational divisions (Savage and Muggah, 2012: 3–4).

Contemporary social research across the three frameworks identified above suggests that it utopian, however, to pursue some kind of urban or societal consensus aimed at ending urban conflict *tout court*. Programs of social homogenization and assimilation driven by projects of state and nation-building and capitalist development, almost by definition, are as likely to generate as to eliminate urban conflicts. Similarly, it is impractical to assume that strategies of urban planning, control, surveillance, or the use of lethal force have the capacity to ensure long-term urban stability. Coercive forms of domination inevitably produce collective resistance. The more constructive or agonistic urban conflicts are those that encourage negotiation, bargaining, and mutual respect among diverse groups as a means of combatting poverty, marginalization, and inequality. It remains difficult in practice, however, to disentangle urban conflicts from the often violent process of state formation and distintegration.

Changing City–State Relationships as a Source of Urban Conflicts

As Tilly (1992) has shown, cities have long been integral to European state formation and the wars associated with it. In the era of city-states, urban conflicts were self-evidently state conflicts. With the emergence of the great overseas and land empires from the sixteenth century onward, and the spread of national states from 1945 onward, cities were increasingly contained and governed by overarching states. States, not cities, became the preeminent stakes in political conflict, the locus of military, political administrative, and ideological power and, additionally, the key regulators of economic power. Consequently, one of the major strands in urban research addresses how state formation and governance have become key determinants of conflict in cities. With accelerating urbanization globally, urban space is increasingly used to make political claims and urban conflicts are constituted by wider intra- and interstate conflicts (Savitch, 2008; Coward, 2009; Graham, 2010; Davis and Libertun de Duren, 2011; http://www.conflictincities.org).

The proliferation of states (from 51 in 1945 to 193 in 2012) has generated much conflict (violent and otherwise) although the scale and intensity of this conflict has fluctuated considerably over space and time. In general, intrastate wars have predominated over interstate wars – the former accounting for an estimated 16.2 million deaths, the latter for 3.3 million deaths in the 60 years after 1945 (Fearon and Laitin, 2003). With the increasing urbanization of the world's population, and the pivotal economic, administrative, and symbolic roles that cities play in national states and in the global, geopolitical system, the changing relationship between cities and organized political violence has come in for increased scrutiny (Graham, 2010; Gregory, 2010; Coward, 2009). Cities have become key sites for the assertion, erosion, and contestation of state sovereignty (Beall and Fox 2009; Davis and Libertun de Duren 2011). According to Graham (2010), the geopolitics of interstate war has generated a new military urbanism, where the city is a 'battle space' provoking a new emphasis on securitization. Here the historical capacity of the most powerful states to externalize organized political violence is undermined, as their own cities become key frontiers of terrorism, counterinsurgency, and crime prevention.

Cities, here, are largely, if not exclusively, seen as the pawns or the victims of the various protagonists of interstate and intrastate wars. While the number of UN recognized states have multiplied, they vary hugely in terms of their infrastructural power (economic, political, ideological, and military). This impacts on their capacity to control, respond to, or exacerbate urban conflicts on home territory or in other, weaker states – for example, in the Middle East, the Balkans, or Africa (Graham, 2010; Beall et al., 2013). As Mann (2012) argues, the core states most deeply embedded in the global capitalist economy in the West, wield greatest infrastructural power. More recently established, poorer states in the Global South or in the historic frontier zones or peripheries of historic empires (Anderson, 2008; O'Dowd, 2012) are less capable of regulating urban conflicts. Weak 'infrastructural power' can be a recipe for generating fear, insecurity, and uncertainty in cities which, in turn, become factories of irregular forms of pro- and antistate violence ranging from criminal activity to organized conflict rooted in ethnic, racial, national, or religious antagonisms (www.conflictincities.org; Bollens, 2007). Such cities risk becoming 'decivilized' by new and repressive forms of communitarianism, and routinized informal violence in everyday life.

An alternative understanding of the state–city interface finds in the very vulnerability and complexity of large cities, antidotes or capacities to combat or decompose organized political violence over the state. Here the totalizing and polarizing thrust of much state-related violence finds an antidote in the differentiating capacities of cities, their shared institutions of civil society, innovative forms of economic development, creativity, and mutual interdependence, and their shared rules for governing relationships between culturally diverse populations (Varshney, 2002; Sassen, 2010). Cities in this view have the potential to be sites of regulated public contest between multiple groups struggling for power, recognition, inclusion, and self-affirmation. 'Open cities', lodged in complex global interurban interconnections (economic, political, and cultural) also have the potential to help create a transnational civil society, which promises to moderate, if not eliminate, wars over bordered national states.

Capitalist Dynamics and Urban Conflicts

A second strand of research emphasizes the rise of neoliberal capitalism globally and the way in which it has diminished the role of states in shaping urban conflicts since the 1980s. The state–city interface is now seen to be no longer so important as commodification, privatization, and deregulation reduce the capacity of states to provide urban social services or mitigate enhanced socioeconomic inequalities. These trends are most apparent in the weaker, more fragile states of the Global South,

faced by unprecedented urban growth. As cities are reordered according to the logic of the neoliberal market, states are less likely to be a focus for individual or collective demands for citizenship rights. Urban conflicts become more fragmented and differentiated in everyday struggles over housing, clean water, schools, policing, physical safety, and the right to use the streets to make a livelihood (Bayat and Biekart, 2009). State accountability becomes an ever more remote prospect in urban contexts formed by a kaleidoscope of corporate interests, corrupt states, pro- and antistate paramilitaries, rival gangs, and informal urban settlements sustained by subsistence economies.

At one level, then, cities are conceptualized as key drivers of economic growth and urbanization, i.e., as central to the operations of corporate capitalism, the rise of megacities and the restructuring, segmentation, or hollowing out the power of national states (Taylor, 2004; Harvey, 2012; Sassen, 2012 – for a critique of this perspective, see Therborn, 2011). At another level, these same cities are the sites of hugely diverse, and often violent, urban conflicts rooted in ever-widening social disparities. Seen through this lens, urban conflicts are fundamentally capitalist conflicts and, directly or indirectly, manifestations of class struggle.

Harvey (2012: 5) argues that contemporary cities have arisen through the geographical and social concentration of a surplus product and that capitalism needs urbanization to absorb the surplus product that it continually produces. The control over the disbursement of surplus, including the ownership and control of cities, typically lies in few hands (Harvey, 2008: 24). Capitalist crisis polarizes wealth further and produces cities that are kept under constant surveillance in gated communities and privatized public spaces (2012: 15). Drawing on Lefebvre, Harvey (2012: 25) recognizes that there are a multitude of diverse struggles over 'the right to city' but he goes beyond the theorists of agonistic pluralism to hold out the prospect of an emergent unity that would pit the 'People' against the 'Party of Wall Street' (2012: 164). For Harvey, gaining control of "the inner connection between urbanization and surplus production and use" (2012: 25), can contribute to the overthrow of contemporary finance capitalism.

From this perspective, the significant urban conflicts are viewed through the lens of class struggle over property, human rights, and other urban resources. This allows for a trans-historical and transcultural approach, which can applied, for example, to the evolution of the Western capitalist city, the colonial city, and the rapidly developing cities of the Global South in the twenty-first century.

There is a substantial comparative and historical literature on urban riots that explores the complex ways in which class divisions interact with other social divisions – how economic inequality fuses with other factors ethnic, racial, gender, and political divisions to fuel periodic, if recurring, violent conflict (e.g., Gilje, 1996; Arrom and Ortoli, 1996; Brass, 1996). Some of this comparative research also addresses state–city relations, notably the issue of policing (Waddington et al., 2009) and the existence of urban-level 'riot systems' (Brass, 1996) while at the same time, recognizing the way in which these issues are framed by a wider economic system that generates social inequality and exclusion.

Writers, such as Wacquant (2008), concentrating on Western Europe and North America, study the scope, spread, and intensity of marginality or socioeconomic seclusion in the city. Here too capitalism shapes the state, but the latter is a more coherent force than its counterpart in the Global South. Wacquant (2008) contrasts the experience of the American city, where ethnicity is amplified by the state and trumps class, with the Western European city where 'class' (and the class-structured state) in the key determinant of social segregation and marginalization as in the multinational French banlieue riots of 2005 (see also, SSRC, http://riotsfrance.ssrc.org). US literature on urban riots, for example, tends to concentrate on the nexus in the inner city between race, ethnicity, and socio-economic inequality and the responses of the police and legal system. In the French suburban riots of 2005, Wacquant (2008) portrays the state's role as more direct as it has been shaped by historical forms of institutionalized forms of class conflict that have forced it to mitigate urban inequality through universalist social provision or targeted interventions. Wacquant here adopts a Bourdieusian or Weberian approach to the city that sees it as site where various forms of capital – economic, cultural, social, and symbolic – are accumulated in ways that are shaped by the state. For him, the struggle to claim or protect these forms of urban capital is at the root of urban conflict.

There is a huge and varied tradition of empirical research on urban conflicts that does not link them directly to class struggle in the strictly Marxist sense. For these studies, capitalist dynamics are mediated through a complex of specific local, regional, and historical structures of power, domination, and resistance. They conceptualize the city more as a dependent rather than an independent variable in its own right (see framework three below). The focus is on how imperatives of commodification working through urban planning, tourism, property development, gentrification, inward investment, and big sports projects dramatically displace and relocate disadvantaged populations (including migrants), the homeless, the poor, and the disabled from desirable urban sites (e.g., Marcuse and Van Kempen, 2002).

Infrastructure may be conceived as a material manifestation of urban conflicts typically resolved in favor of the powerful (Rodgers and O'Neill, 2012) or resisted (sometimes temporarily) by the disadvantaged and the poor. Thus, the gated communities, the wealthy suburbs, the banal, and homogenized urban public spaces are one side of a process driven by a desire on the part of elites and middle classes to distance themselves from direct social contact with the 'dangerous' classes because of the latter's proclivities to criminality, disease and violence. The deep and multiple social inequalities that flow from the capitalist system may be experienced differently in working class Parisian suburbs than in the favelas and shantytowns of the new megacities, however. Local and regional differences remain significant in shaping the form of urban conflicts. For example, there are no counterparts in Middle Eastern cities to the lethal drug gang wars in Mexican and other Latin American cities (Rodgers, 2009; Molloy, 2013). Similarly, the conflicting urban fiefdoms of Beirut or the struggle between fundamentalists and secularists in Cairo have their own regional specificities. Nevertheless, the long history and contemporary prevalence of urban riots, protests, racial, ethnic, and sectarian conflicts, gang warfare and criminality may be interpreted as struggles over unequal economic, political, and cultural resources.

Two of the major theorists of urban conflicts, David Harvey (2012) and Manuel Castells (2012) provide somewhat different perspectives on these conflicts although both recognize the ubiquitous influence of neoliberal capitalism. The former emphasizes the primacy of 'class struggle', however, where the latter stresses power inequalities. Harvey continues to emphasize the direct link between urban protests and the contemporary crisis of finance capitalism – assimilating them under the banner of the collective 'right to the city'. Castells' (1983, 2012) work, on the other hand, has moved away from his early structuralist analysis of the capitalist system and the specificity of the 'urban' (Castells, 1977), to the comparative study of urban social movements. He conceives these as grassroots phenomena, that are spontaneous, often temporary or transient, and prone to co-option or disappearance. He argues that they continue to challenge the multiple structures and forms of power and domination to be found in cities across the globe. For Castells, however, these urban conflicts are less coherent and more unpredictable, than in Harvey's analysis that links them rather more directly to the nexus between urbanization and capital accumulation.

The 'City' as a Source of Urban Conflicts

The third research strand draws on theories of the 'urban' per se, where the city itself is treated as a causal variable in generating and shaping distinctive patterns of human behavior and culture (Wirth, 1938; Jacobs, 1961). This approach has been typically associated with periods where cities develop highly visible characteristics that sharply distinguish them from their immediate hinterlands (or the rest of state territory) – for example, Chicago in the early twentieth century, the colonial city at the zenith of Western imperialism and colonialism, and more recently, the rapidly expanding cities in 'developing' countries. Within this framework, urban conflicts are seen to arise directly from the sociospatial and physical environment. Alternatively, anthropologists ascribe to cities a mythology, charisma, or soul, which help to constitute their particular urban conflicts (e.g., Hansen and Verkaaik, 2009).

While these perspectives accord cities an integrity and distinctiveness of their own that is not reducible to political economy, they also acknowledge the impact of the state and economy on urban conflicts. The association of cities with conflict, violence, disorder, poverty, and a range of other social problems is rooted in the Western intellectual response to the growth of the industrial city. Moral outrage over the ills and evils of urban life have typically shaded from ambivalence into outright antiurbanism (White and White, 1962; Williams, 1973) in the context the portrayal of social change as framed by rural–urban, country–city, and gemeinschaft–gesellschaft distinctions. Angotti's (2006) critique of Davis (2006) has trenchantly argued that this tradition continues to survive in contemporary Western views of the megacities of the Global South. These analyses tend to see cities as 'things' that produce all manner of urban ills (including mass poverty, violence, and disorder) rather than as complex sets of social relationships, which provide multiple opportunities for progressive, grassroots urban movements to oppose oppression and create democratic institutions.

The most systematic and empirically grounded example of the tradition that sees the city as an independent variable in its own right remains the work of the Chicago School of Sociology (1890–1940). This culminated in Wirth's (1938) famous theoretical synthesis. Wirth proposed a universalist definition of the city as a "relatively large, dense, and permanent settlement(s) of social heterogenous individuals" (1938: 8) that produced varied forms of social disorganization, conflict and 'deviant behavior'. Although much criticized for their reliance on biological/ecological metaphors and its conservative and ethnocentric biases (e.g., Rodgers, 2010), the influence of the Chicago survives in many social scientific and planning approaches to the city.

The 'Chicago' approach also pioneered the practice of according 'exemplar' or 'paradigmatic' status to key cities (Beauregard, 2003), because they are deemed to be stereotypical or generic, archetypal, or prototypical – a trend setter (Brenner, 2003: 208). This approach is an attempt to impose a degree of analytical manageability and coherence on the huge population of highly diverse historical and contemporary cities. Typologies (either explicit or implicit) are thereby generated while a small number of key exemplars of each type get intensive research scrutiny. Contemporary examples include the 'global city', the capitalist city, the industrial city, the '(post)modern city', the 'fundamentalist city', the 'postsecular city', 'contested cities', and 'cities of the Global South/North'. These conceptualizations influence the interpretation of urban conflicts deemed to be characteristic of each type.

Anthropologists typically rely on 'cultural' analyses to provide more holistic interpretations of cities and their complex conflicts. For example, Hansen and Verkaaik (2009) employ the concept of urban charisma as embedded in people, things, places, and situations (2009: 8). They suggest that the urban must be understood as "a way of being in the world, as a dense and complex cultural repertoire of imagination, fear and desire" (2009: 5). As such urbanism is defined differently than in the Chicago School – cities are not reducible to their functions or the dynamics of their social networks rather they should be understood at several levels as (1) sensory regimes; (2) specific forms of knowledge and intelligibility; and (3) specific forms of power, connectivity, and possibility. The key charismatic urban individuals or urban specialists – big men, hustlers, brokers, even criminals who have extralocal links to centers of power and who link informal urban life to its formal institutions. They register, facilitate and mediate the constant conflicts over urban space between rich and poor, planners and pavement dwellers (2009: 11). In the process, they give cities a form of unity in the face of their multiple conflicts and fissiparous tendencies.

Summary

The research traditions identified above often overlap in practice yet they reveal three important analytical options in the search for the source of urban conflicts. Whether the source is located in state–city relationships, the global capitalist economy, or the city as a distinctive material and social phenomenon, has far-reaching implications for understanding the substance and

potential significance of urban politics. The examples discussed under each heading are merely illustrative of a vast and complex field. While much of this literature has its provenance in the 'West', there is an overall tendency across the three approaches to encompass the study of urban conflicts within an overarching global framework. Nevertheless, the three approaches identified above do not embrace all the relevant literature on urban conflicts notably that which accords more significance to individuals. Gupte (2012), for example, argues that collectivist terms such as ethnic and communal violence might be replaced by the term 'civil violence' which accommodates a more microperspective that better accommodates the agency of individuals. Karl-Dieter Opp (2009) also advances a more capacious framework that synthesizes a range of disciplinary perspectives on political protest and social movements while advancing a structural-cognitive model of his own. This framework seeks to make explicit links between macrostructural perspectives and microperspectives focused on why people participate in different forms of social protest. However, Opp does not link protests and social movements explicitly and systematically to cities or the urban environment.

Urban conflicts have an increasing transnational and transcultural resonance. Despite their vast differences, cities in the Internet age are now embedded in global networks, which make the performance of some urban conflicts iconic and instantly communicable. These conflicts also highlight shifting relationships between violent and nonviolent strategies. Wars are increasingly urban. Cities now rival states as arenas and stakes in political conflict. Struggles between rich and poor, Al-Qaeda bombing campaigns, the 'Arab Spring' protests, the 'occupy' movements, drugs wars in Latin America or sectarian violence in Asia and Africa all demand specific historical analysis. However, they are also reshaping cities in recognizable patterns that demand more sustained comparative study.

Urban Design and Public Space

Ali Madanipour, Newcastle University, Newcastle upon Tyne, UK

Abstract

Public space is a primary ingredient in urban environment; places of encounter where public life unfolds. Following structural changes in economy and society since the 1970s, it became a focus of attention in a shifting division of labor in spatial production, raising anxiety about the role of the state, decline of public services, and privatization of urban environment. It is acknowledged as a vehicle of urban regeneration and sustainable development, an essential part of building competitive and compact cities, based on services and experience economy. However, concerns about social and environmental consequences of globalization, consumerism, urban spectacle, and gentrification remain.

Public space has increasingly become a subject of inquiry for different disciplines and professions (Carmona et al., 2008; De Souza et al., 2012; Hou, 2010; Low and Smith, 2006; Orum and Zachary, 2010; Parkinson, 2012; Sadeh, 2010; Watson, 2006). How can this rising interest be explained and why is there such a new emphasis on a subject as old as the city itself? Public space is one of the primary ingredients that make up a city, ingredients that in one form or another have continually been part of the vocabulary of urbanism. A city is an agglomeration of people, where developing a common infrastructure of institutions and spaces is an essential prerequisite for making collective life possible. As the remains of the earliest cities show, human settlements have always been formed by an accumulation of household territories linked together through common spaces such as streets, markets, and temples (Benevolo, 1980; Morris, 1994). By now, therefore, after centuries of making and remaking cities, we should have worked out how to develop and maintain our common infrastructure; so why should there be intensified attention paid to this subject? In this article, I will examine the theme of public space, and urban design as the process of shaping urban space, in the context of the major social and economic changes that have transformed the now predominantly urban world. Investigating the organization of space in ancient ruins gives the archaeologists some understanding of how society was organized in these lost cities. If we study our contemporary urban spaces, what can we learn about our society today? If public space is a subject of renewed interest, should it be seen as a necessary ingredient in facilitating and supporting urban change? Or might it indicate an anxiety about change, rendering us no longer able to travel on a well-trodden path? What are the possible causes and consequences of these changes for the urban society?

Anxiety for Democratic Urbanism

The concern about public space is partly rooted in the structural changes in society that endangered the provision and maintenance of public services (Madanipour, 2011). The 1970s marked the end of a model of economic development based on a tight regulation of the market by the state, and of the direct involvement of the state in the production of the built environment. During the nineteenth and twentieth centuries, urbanization went hand in hand with industrialization, bringing people into cities at ever larger numbers and faster rates, resulting in a continually unstable combination of high productive capacities and poor living conditions. The global economic crisis of the 1930s, social upheavals in Europe, and the Second World War had encouraged western governments to take a more active role in the economy, stimulating demand through a better distribution of resources and improving the conditions of life in cities. Public investment in essential public services such as health, education, transport, and housing increased through direct involvement by the state.

The planning and design ideas that had been developed in an earlier period, from Ebenezer Howard's garden cities (Howard, 1965) to Le Corbusier's city of future (Le Corbusier, 1987), were now employed to construct houses, roads, schools, hospitals, and new towns. Modernism and garden cities movement became the twin design ideas that shaped the twentieth century cities (Jacobs and Appleyard, 1987). Le Corbusier had called for 'architecture or revolution' and Howard's book was subtitled, 'the real path to reform.' Industrial technology and functionalist design were used in the mass production of the built environment, justified by social concerns. These ideas, in turn, were routed in a long history of social reform and utopian thinking that had originated from the Renaissance ideal cities and continued up to the urban improvements and the model towns of the eighteenth and nineteenth centuries. While these ideas had been implemented in small-scale experiments, they were now implemented systematically through comprehensive planning. The twentieth century was a century of organizations (Aglietta, 2000), as partly reflected in the complexity and expansion of the state and the emergence of a mass society, the manifestation of which could be visibly seen in the development and transformation of the built environment. Provision of public open space was one of the key demands of these changes, as indicated by the Charter of Athens, demanding for new breathing spaces in the overcrowded and badly built cities (Sert, 1944).

This model of development, however, ran out of steam by the 1970s, which became a turning point; the following decade witnessed the start of a new phase, in which the Keynesian accord between the state and the market was broken. The role of the state in urban development changed in accordance with

epochal shifts in the economy. Technological innovation in information, communication, and transport transformed working practices, manufacturing industries were relocated to lower cost regions of the world, and the global map of economic production was redrawn. Structural change eroded the state's ability or willingness to invest in, and the urban populations' strength to demand for, public services. The size and scope of the state was reduced, so as to open up new spaces for the market to rejuvenate. State institutions now saw their role as enablers rather than producers, paving the way for the market rather than directly engaging in urban development. The midcentury urban renewal projects had not only failed to solve the social problems, they had now become a new social problem themselves, demanding urgent attention. The accelerated process of deindustrialization, casualization of the labor force, international immigration, and dwindling public budgets threatened the provision and maintenance of public services. Urban development projects were no longer planned and implemented by the public sector, which was now seen to be bureaucratic, clumsy, and ineffective. The end of the social democratic phase led to a period of neglect for public spaces and public institutions.

The new laissez-faire phase that started in the 1980s transformed the organization of spatial production. The rundown industrial sites, and later city centers and public housing schemes, were opened up to a new model of development, in which private companies were supported by public subsidies to take on the role of urban development and regeneration. Private firms, however, had a limited remit, obliged to provide a return on the investment of their shareholders, rather than delivering services for the general public. If public authorities were not making or maintaining public spaces, how could private firms be expected to do so? This question opened up a crisis of confidence and a rising sense of anxiety about how, to what extent, and by whom, should public services be provided. For their urban development projects to function, private developers needed some form of intermediate space, providing access to properties, as well as representing the development as a whole to the possible customers. But developers desired to control these spaces, especially if they were on private land, so as to ensure the comfort and protection of the users and to safeguard their own investments. The regeneration of cities after industrial decline often meant investing in parcels of land surrounded by a sea of decline, where new upmarket areas could be transplanted in the middle of a deprived district, a disconnection that could find social manifestation, such as resentment, anxiety, and fear, and spatial forms such as highly guarded, walled, and gated areas. In an increasingly unequal society, the copresence of the two ends of the socioeconomic spectrum could be interpreted as undesirable and even dangerous. Public space was increasingly associated with homelessness and crime, to which the private reaction was fearful withdrawal, and the policy response was forceful conquest, both with negative social consequences. Privatization of public space could shield the higher income users of these spaces and keep the lower income groups and undesirable activities out, while gentrification and heavy-handed policing would displace them. This was a crisis for public space, and by extension a crisis for the city as a whole.

The campaign against gentrification and the privatization of public space, therefore, had a wider anxiety about the loss of the idea of the city, and the disabling impact of social inequality and exclusion on democratic practices. The western liberal democratic tradition had long encouraged the development of an active public sphere, in which citizens were able to participate, communicate freely, and develop opinions about the affairs of their society, which would enable them to make informed political decisions in democratic governance. The heritage of the enlightenment was based on the idea of generating and sharing information and knowledge, as exemplified by the British coffee shops, French salons, print newspapers and pamphlets, collective efforts in writing dictionaries and encyclopedias, all part of the emerging democratic nation states. Major theorists of public sphere, such as Habermas (1989) and Arendt (1998), attempted to show how this public sphere was an essential ingredient of a well-functioning democratic life. If the public sphere was controlled by the private corporate world of the property developer and the media tycoon, how could such democratic traditions be maintained and improved? Anxiety about public space was an anxiety for the urban society and for democracy. The loss of access to public space meant a decline of democracy, as the primary condition for a place or activity to be public is access (Madanipour, 2010).

The Challenge of Diversity

With its roots in the Latin word for people, the word 'public' indicates people as a whole, which is often defined in contrast to the private sphere, which is the sphere of individuals and households. The liberal political theory has argued for maintaining a clear divide between the public and the private spheres, so as to avoid corruption (Nolan, 1995; Wacks, 1993). The interplay of concealment and exposure, i.e., some control over what is revealed to others and what is kept hidden from them, remains an important dynamic in social and political life (Nagel, 1998). Encroachment of the public sphere into the private sphere would result in the loss of privacy and individual freedom, while the encroachment of the private sphere into the public sphere may create individual gain and collective loss. There are, however, difficulties with thinking about people as a uniform whole, as any society is made up of a range of different types of people, and ultimately of a multitude of individuals each with a different life story and trajectory. As the campaigners for different minority or disadvantaged groups have argued, the notion of the public in law and politics has historically been based on a narrow basis, ignoring the diversity of the population to whom the law applies. The public sphere is made up of many social and spatial ingredients, which include the public spaces of towns and cities. Many cities have historically emerged at the meeting points of major roads, and public spaces of cities, which took shape around these intersections, may be broadly defined as crossroads, as places of encounter where the life of the city unfolds. It is here that diverse populations may meet, their trajectories collide or coincide, and where the different spheres of political action, sociability, economic exchange, and cultural performance may play out through instrumental and expressive means (Madanipour, 2003).

Anxiety over public space is not only about sociability, equality, and democracy; it is also about the loss of community, which is a long-term problem of modernity. The populations of the small agrarian towns had developed tight cohesive interrelationships, which were shattered as these populations were uprooted from their towns and villages and brought by force or encouragement to large cities as paid workers. The early students of urban societies (Engels, 1993; Tönnies, 1957; Simmel, 1950) were horrified about the conditions of these newcomers, interested in the way metropolitan crowds were alienated from one another, anonymous and atomized, withdrawing into a small mental space that would allow them a degree of psychological safety. Many romantics, revolutionaries, and reformers who observed the life of large cities recommended a return to the countryside, even dismantling large cities, by force if needed, or at least the reconstruction of smaller communities in which a sense of cohesive relationships could be developed. Others advocated the creation of new religious or secular bonds inside cities to help develop new communities.

In these communitarian ideals, public space played a significant role, as a place in which people of a small community could be linked to one another (Taylor, 1995; Etzioni, 1995). The possibility of recreating such communities, of course, is in serious doubt, as the forces of mobility, diversity, individualization, and metropolitan growth are not showing any slowdown. The design ideas that were used in this laissez-faire stage were all a rejection of the modernist functionalism, advocating playful juxtapositions or a return to the premodern city. Communitarian ideas have been a strong influence on these design directions. A return to the idea of garden cities, as shown in new urbanism and urban villages, has often been based on the centrality of public space as a cohesive force in spatial and social organization. In practice, however, it can only help create a semblance of a community, an appearance that may or may not in the long run turn into a cohesive social phenomenon. In a mobile society, the possibility of developing long term social bonds is reduced, and the image rather than the practice of cohesive urban life may be what might be possible.

Public space, in its physical form, no longer plays the crucial role that it had once had in urban life. In the smaller cities of agrarian societies, the public space was simultaneously a place of sociability, trade, religion, and politics. The central public spaces of the city were places of high theater of power by the religious and political elite of the day, placing their highest towers, most magnificent buildings, most elaborate works of art, their most impressive statues and fountains, so as to produce a social order through symbolic means. However, the growth of the large industrial city, the transformation of the cultural norms, the breakup of the social bonds and the atomization of urban populations, the mediated and mass forms of communication, and the complexity of political and economic processes all splintered the public events into many different locations. The symbolic and the functional values of the public space were taken over by the high rise corporate offices in the new cities, indicating the cathedrals of the newly powerful. The symbols that were inherited from the past were transferred to an aesthetic sphere, but the public space kept some of its earlier values, as evidenced by political demonstrations and campaigns as well as a place of everyday sociability and intermingling. What constituted public space was the possibility of copresence and face-to-face encounter, which remains the most potent form of social interaction. Much hope has been placed in the communicative possibilities of the information and communication technologies, which have created the possibility of forming new social networks and new spaces of possibility across the world. These technologies, however, are essentially libertarian, allowing individuals to keep a distance from others and cut their links as easily as setting up those links. The strength and potential durability of social connections that face-to-face encounters could bring about were exposed to further pressures of contingency and ephemerality.

A Shifting Division of Labor

The campaign for public space, which started to grow from the 1980s onward, was a central theme of urban design. In its broadest sense, urban design is the process of shaping cities. It plays a vital part in the production of the built environment, with significant political, economic, and cultural dimensions, going beyond appearances, limited scope and scale, and mere physical transformation. In the common use of the term, design is sometimes limited to form and appearance, visual expression and aesthetic experience, and so restricted to beautiful objects and luxury lifestyles, branding and superficial treatment. Design, however, goes beyond appearances; it also addresses the function and use of objects, as well as providing instructions for making them. It reorganizes space and signifies cultural meaning, political performance, and economic value. Design in its modern sense was seen as a sign of applying order and rationality, in contrast to the accidental and piecemeal development of medieval cities (Descartes, 1968). Design, therefore, is a plan, purpose or intention, articulated by visual or other means, envisaging a finished outcome and instructing how it should be made. It involves "the playful creation and strict evaluation of the possible forms of something, including how it is to be made" (Lynch, 1981: p. 290). It deploys creativity, as 'the generation of new ideas,' toward innovation as 'a specific end' (Cox, 2005: p. 2), as well as offering a code with which the contemporary society can be understood (Sudjic, 2009: p. 49). When it is applied in shaping cities, therefore, the role of design is wide ranging in scale and scope. It goes beyond the narrow scope of townscape beautification or the limited scale of the spaces between buildings, to engage in transforming significant parts of urban areas or even the design of entire new towns and cities. This purposeful process of shaping cities is not limited to physical transformation, but also includes a wide range of economic, political, and cultural considerations.

The roots of urban design go far back to the dawn of urban living 10 millennia ago, as living in towns and villages has always required thinking about how to build and transform them in such a way as to support life of a large number of households living together in a limited area. The remains of the earliest cities are the evidence of this purposeful thinking: relating one building to another, moving from one place to another, providing places of significance, and relating the town to its surroundings, all reflecting and consolidating social structures and habits in a human agglomeration. Urban

design in its current form, meanwhile, emerged as a response to the changing division of labor in spatial production. As the state withdrew from urban development, urban planning lost much of its remit and ability to envisage the future shape of the city and to shape the urban environment through forward planning. Envisaging the future of the city in an uncertain world seemed like a futile enterprise, and the previous generation who had engaged in this visioning was condemned as utopian.

As planning moved toward policy development and implementation, it severed its ties with architecture and abandoned the development of design skills. Rooted in the modernist tradition, these skills were thought to be merely involved in aesthetic considerations, rather than rational calculation, which increasingly seemed to be possible by computers. Land-use planning, therefore, became limited in responding to the initiatives of the market, rather than initiating change on behalf of the local authorities. Architects, on the other hand, lost their sense of confidence in redesigning the city, as the postwar experiments were seen to have failed and as the public and private sectors were renegotiating their relative roles and powers. Architects were now primarily part of the private developer's team, limited to the confines of the site and the interests of the client, rather than the wider problems of the city. The social rhetoric of modernism had already been abandoned once its ideas were taken over by the large private corporations, but it had survived in the public urban development schemes, which were now lost as a result of structural change. Urban design emerged to fill a gap, providing the necessary skills and knowledge to design and transform parts of cities. The new pattern of urban development involved a number of stakeholders from the public and private sectors involved in potentially fragmented schemes, which now needed direction and coordination, delivered through master plans for large-scale projects and emphasis on public space as an integrative force, linking various stakeholders together and mobilizing them around a shared vision. After several phases of change, planning eventually embraced a strategic spatial form, which would allow it to focus on a particular area of the city, as a pragmatic use of the limited resources focusing on the most troubled parts of the city with the highest potential for economic revival. It was through urban design master plans and strategic spatial plans that urban design and urban planning came closer to one another once again. Large-scale urban projects became the vehicle of mobilizing resources for urban regeneration (Lecroart, 2007).

While the technical division of labor has been shifting to find a proper deployment of the necessary knowledge and skills, there has been a campaign for intensifying participatory practices, which would compensate for the democratic deficit of this technocratic effort. Public participation, in a sense, is the process through which the production of space can become inclusive, as a counterweight to the exclusionary social pressures and the narrow focus of the economic agendas (Madanipour, 2010). If genuinely open, it has the potential to offer a better chance of delivering inclusive public spaces. The question, however, often revolves around the extent of participation: is it led and framed by the elite to legitimize their decisions or is there a genuine space for coproduction in the process?

Economic and Environmental Rationale

The initial stages of economic and political restructuring coincided with rising anxieties. These stages were followed by a new wave of optimism, as public space was eventually placed on the agenda of the urban development. The early shocks of deindustrialization and radical liberalizations were partly moderated by the idea of sustainable development, with its blend of social, economic, and environmental concerns. From international organizations such as the European Union down to national governments and local authorities seemed to accept the necessity of investing in public space, and many municipalities around the world have developed programmes of public space development and improvement. The division of labor between the public and private sectors have been continually shifting, always leading to controversial outcomes when substantial parts of the public sector roles and duties were taken over by the private sector. Now that housing and intervention in the private property was no longer a public sector remit, its shift of focus on public space could help it find legitimacy and visibility, recovering a spatial platform in the urban development process. This new attention is often associated with economic, social, and environmental justifications.

In the globalized economies, cities are the engines of economic activity, as evidenced by the restless growth of urban populations around the world, changing the demographic balance in favor of cities for the first time in history. As the two State of European Cities reports show, larger European cities show a trend of growth in population and in the accumulation of wealth, while the middle sized cities have stagnated and peripheral regions decline (ECOTEC, 2007; RWI et al., 2010), an uneven pattern of development which has been exacerbated by the global financial crisis. The competitiveness of cities, therefore, has become a key consideration for policy makers, hoping to ensure this capacity through innovation and attractiveness, both with significant roles for public space.

The European Union's 10-year strategy, EU 2020, advocated 'smart growth,' which was "an economy based on knowledge and innovation" (EC, 2010a: p. 5). The transition out of labor-intensive manufacturing industries was to lead into knowledge-intensive services and higher levels of added value. Innovation, therefore, lay at the heart of the new economic activities, in science and technology as well as in cultural and creative industries, which were involved in utilizing the information and communication technologies and high skilled workers in developing new products, encouraging consumption through the 'experience economy' and setting and amplifying social and cultural trends that could stimulate consumer demand (EC, 2010b: p. 17). Innovation drew on the meeting of minds, the social encounters that would facilitate collaboration and exploration, partly made possible through a vibrant urban environment.

Attractiveness, meanwhile, was another way that urban public space was envisaged to contribute to economic competitiveness. Cities found a decisive importance in the EU Lisbon Strategy, which advocated making Europe "a more attractive place to work and invest," and as most Europeans lived in urban areas, the "attractiveness of European cities" was

thought to "enhance their potential for growth and job creation" (EC, 2006: p. 1). In this context, the role of public space becomes recognized by the Leipzig Charter, signed by European ministers of development in 2007, who saw public spaces as "soft locational factors," which are "important for attracting knowledge industry businesses, a qualified and creative workforce and for tourism" (EC, 2007: p. 3). Economic competitiveness, therefore, was thought to be achieved through innovation, which in turn was aided by an attractive and vibrant urban environment, a crucible in which new ideas and practices could be developed through intensified communication and exchange. The idea of the death of the city, which was once imagined as inevitable (Martindale, 1966), has become only a fading memory. Rather than disappearing under the pressures of mobility and communication technologies, cities have grown larger, reflecting and intensifying the need for copresence as an economic force. In addition to economic value, public spaces were also acknowledged to have environmental significance.

Cities have major responsibilities in both creating and finding ways of addressing the problem of climate change. As the Aalborg Charter, signed at a meeting of European towns and cities in 1994, admits, "We understand that our present urban lifestyle … make us essentially responsible for many environmental problems humankind is facing" (EC, 1994: p. 1). The lack of open space, the Charter maintained, was one of the core environmental problems. Search for individual comfort and quality of domestic space had led to urban sprawl, which had adverse effects on society and environment, consuming higher rates of energy and land, generating higher levels of traffic, air, and noise pollution (EEA, 2009). Compact cities, with their mixed land use and high density and reliance on public transport, have been identified as a way of reducing energy consumption and protecting the environment from encroachment by the city. Living at high-density compact urban environments, however, needs to be facilitated and supported by the provision of high quality public open space. Public open space, therefore, becomes a central theme in the policy documents that advocate sustainable development (EC, 2007; EC, 2010c). The vision of a sustainable city envisages "safe areas, green, and other public spaces, as well as … short distances to facilities and services," which would make them "sufficiently attractive to counter urban sprawl" (EEA, 2009: p. 40). As the European Environment Agency puts it, "Urban areas need to provide for their citizens the foundations for choices leading toward more sustainable lifestyles, such as affordable housing in more compact urban areas that provide high quality public spaces and a healthy environment" (EEA, 2009: p. 102).

Anxiety over the privatization of public space and the delivery of public services triggered the initial phase of campaign for public space. Now that many national and international organizations have acknowledged the significance of public space in urban life and many municipalities have active programmes of public space improvement, should the old anxieties be put to rest? If the public space agenda is now so strongly supported by the state, have the problems gone away or at least a path is established for dealing with these problems?

From Old to New Anxieties

Some signs indicate that there are grounds for new anxieties, as public space improvement may serve as a pathway to gentrification and consumerism and the capacity for its improvement may be jeopardized by the decline of public finances. The economic phase that started in the 1980s has in turn come to a halt with a new global economic crisis in 2008, which has demanded massive intervention by the state, but this time saving the banks as the infrastructure of the market, rather than a return to direct intervention in the economy, indicating the possibility of deepening the laissez-faire directions, rather than a return to the social democratic phase.

Economic austerity and dwindling public finances may limit the future projects of public space improvement, triggering a new, intensified phase of concern over the provision and maintenance of public services. As the opening words of the European Union's 10-year strategy, EU 2020, put it, "Europe faces a moment of transformation. The crisis has wiped out years of economic and social progress and exposed structural weaknesses in Europe's economy" (EC, 2010a: p. 5). The economic crisis has been so deep that the ability of the governments to maintain their commitments to public service delivery has been stretched to the limit. In this context, the future of public space as an inclusive and accessible place may come under pressure. Austerity, however, is not a universal problem and many cities around the world continue to grow in size and prosperity, and carry on investing in their public spaces. The problem in these cities may lie in the way public services and public space are conceptualized and delivered.

Some have called the new phase in economic production as spatial and immaterial, hinting at the nature of digital streams that can turn into profitable commodities. The globalized economy, however, is based on an intensified production and consumption of material products (Madanipour, 2011); people's lifestyles in wealthy cities have never been more entwined with a larger number of material possessions (Sudjic, 2009). A new global division of labor has enabled the relocation of manufacturing from some cities to others, opening up new productive capacities, which require an expanded capacity for consumption. What has been called a consumerist society is the foundation of the global economic relationships, as without intensified consumption, the global economic relations of intensified production and exchange would collapse. The impact of consumerism on the urban space has been enormous, as economic regeneration in many cities has been made in the form of new shops, restaurants, and spaces of leisure, encouraged through an 'experience economy,' in which the urban environment is envisaged as a spectacle. Public spaces play a central role in the development of spaces of experience and in encouraging consumption, to the extent that they might be even seen in some instances as the preconditions for the development of new consumerist activities in an area. So the question becomes, is this the reason why public space has become a key commitment by the municipal authorities, who think they need to follow the market's lead and see consumption-based activities as the only way of economic revival and political legitimacy?

Globalization and state entrepreneurialism have also encouraged cities to behave as firms, thinking of citizens as customers, and public authorities as managing directors of corporations in competition with other corporations from around the world, attempting to attract investment. The basic assumption is that a city needs to attract the floating resources, which can be captured through a variety of means from mass tourism to new companies. Investment in the quality of public environment is one of the key elements of this strategy, which helps branding places as commodities for sale. It is with the same logic that cities compete for having the tallest buildings, recruiting the most famous architects, and developing the most expressive architectural forms. The question, however, is whether the local investment in public infrastructure is steered toward the needs of these outside investors or it also includes the needs of the local citizens. If one is ignored at the cost of the other, the result would be differential treatment, fragile spaces, uneven development, and an unequal society.

A new anxiety emerges about the impact of public space development on the vulnerable communities in deprived and rundown parts of cities. Is the emerging interest in public space improvement coinciding with an interest in the fate of deprived neighborhoods, or would investment in public spaces be a stepping stone to gentrification of urban areas, pricing out existing communities and replacing them with people who have stronger financial abilities? The positive contribution of investment in public spaces to the improvement in the quality of urban life has to be acknowledged. The question is whether such improvement is beneficial for everyone, or that it serves some at the cost of others. Concern over the lack of public space, which was a symptom of a particular model of development, may therefore turn into a concern over the impact of public space provision on public life. An uneven pattern of development, both within cities and between cities, has been noted even in Europe, where the tradition of the welfare support is still strongest in the world (ECOTEC, 2007; RWI et al., 2010). Added to inequality is the challenge of social diversity, which is fueled by the plurality of lifestyles and the intensification of mobility and migration. Investment in public spaces of the deprived neighborhoods, therefore, may be thought to contribute to social inclusion of the marginalized groups (Madanipour, 2010). Similarly, the environmental imperative requires attention and investment in urban public spaces. The question is whether in the context of new economic conditions the willingness and the ability to invest in these areas will not suffer (Madanipour et al., 2014).

Urban Entrepreneurialism

Andrew Wood and Timothy Brock, University of Kentucky, Lexington, KY, USA

Abstract

Urban entrepreneurialism is a concept developed by the geographer David Harvey to characterize a profound change in the period after 1970 in the way capitalist cities are governed. The article defines urban entrepreneurialism, its distinct characteristics, and the range of urban strategies that are associated with the entrepreneurial city. The article examines how the concept has been deployed since its introduction in 1989.

The term 'urban entrepreneurialism' is used to characterize a broad historical shift in the way in which the cities of the capitalist world are governed. The term dates to an annual address by the prominent geographer David Harvey to mark his receipt of the Anders Retzius Medal by the Swedish Society for Anthropology and Geography and was subsequently published in *Geografiska Annaler* (Harvey, 1989). David Harvey has a long and distinguished record of contributions to the discipline of geography and his influence extends well beyond the field (see Castree and Gregory, 2006 for a review of his work). In what follows, the authors first provide a brief summary of Harvey's argument. While the term dates to 1989, and like all concepts it is rooted in the particular circumstances of the time, the ideas encompassed in Harvey's argument have exerted significant influence on subsequent work. The second section of the article provides a review of the various ways in which scholars have sought to illustrate and examine the different aspects of urban entrepreneurialism set out in Harvey's account. The third section of the article examines the position of the concept in relation to subsequent developments in how one might best theorize and investigate the changing political and economic dynamics of the capitalist city. While the concept jostles for position with more recent contributions, the arguments that underpin urban entrepreneurialism continue to have lasting resonance.

Urban Entrepreneurialism Defined

The concept of urban entrepreneurialism is rooted in David Harvey's general interest in the historical relationship between the process of capitalist development and its manifestation in the urban landscape or the 'built environment' (Harvey, 1978, 1985, 2003). Harvey's work has traversed a variety of geographical contexts and scales, although the concept of urban entrepreneurialism is very much rooted in the study of the contemporary capitalist city. His book *Social Justice and City* (Harvey, 1973) marked Harvey's turn to the theoretical framework developed by Marx and by subsequent Marxist-inspired scholars. The analytical strength of urban entrepreneurialism lies in its ability to bridge the powerful insights of a Marxian account of capitalist development with the particular ways in which the place and management of cities have changed over the past 50 years.

Harvey argues that the 1970s and 1980s had been marked by a series of changes in the way in which economic and political interests sought to govern the city. The dominant approach to that point was one of 'urban managerialism' in which the state and its various agencies served as the key locus for administrating or running the city. Using ideas similarly inspired by Marx, Manuel Castells had developed an influential argument that urban politics was largely centered on conflict and division around the reproduction of labor power (Castells, 1977). His work on the politics of state housing provision in Paris proved particularly influential for subsequent scholarship on the politics of urban social movements (Castells, 1983). In short, urban managerialism is an approach to governing the city that principally concerns the allocation of resources and services to meet the political demands of different constituencies. Accordingly, urban political conflict is very much centered on struggles over the equitable distribution of state services and resources.

Harvey argued that while urban managerialism was the typical mode of governing the capitalist city in the 1960s, the 1970s and 1980s had seen a general reorientation of the concerns and issues deemed significant to how cities should be run. The period had been marked by the steady emergence of a more 'entrepreneurial' form of urban governance in which local ruling elites had begun to adopt a much more proactive role in seeking to determine the future trajectory of the city. Managerialism has centered on questions of social reproduction, whereas the urban agenda was becoming ever more shaped by the economic fortunes and prospects of the city. Entrepreneurialism reflected the development of what Cox has termed a 'new urban politics' as local economic development took center stage (Cox, 1993).

There are three dimensions or distinguishing characteristics of urban entrepreneurialism. The first concerns the actors engaged in governing the city and here Harvey's use of the term 'urban governance' is particularly significant. Governance reflects the view that the ordering and management of the city encompasses a range of actors beyond those of city government itself. Indeed, urban entrepreneurialism's first distinguishing characteristic is that it is centered on 'the notion of a public–private partnership' (Harvey, 1989: p. 7). Subsequent work in the urban entrepreneurial tradition has commonly sought to describe how 'partnerships' and partnership vehicles in particular cities have emerged.

While formal public–private partnerships are of relatively recent vintage, Harvey recognizes that local business interests have long sought to promote or boost their particular territories of interest. Along these lines the argument clearly resonates with other scholarly work seeking to theorize the politics of urban development. The concept of the urban growth machine developed by Harvey Molotch and John Logan (Molotch, 1976; Logan and Molotch, 1987) and that of the urban regime developed by Clarence Stone (Stone, 1989) are particularly germane. For Harvey, the novelty of the current condition is the way in which the traditional business interest concern with promoting the city "is integrated with the use of local government powers to try and attract external sources of funding, new direct investments, or new employment sources" (Harvey, 1989: p. 7). Key to Harvey's argument is not that local business interests have only recently developed a concern with the management and future trajectory of their city but rather that these interests have increasingly sought to pursue their concerns through the incorporation and use of the powers of the local state. Harvey's argument starts with economic interests and seeks to examine how those interests are realized through the mobilization of state powers. What ultimately drives the activities of those involved in governing the city is the attempt to secure the flows of capital investment and labor that will serve to realize the interests of those vested in the city. The argument certainly lends itself to research examining the history of business–state relationships at the urban scale, although work deploying the concept has very largely focused on contemporary circumstances.

The second feature of urban entrepreneurialism is the speculative nature of the activities undertaken by the partnership and, in particular, the distribution of the risks associated with these activities. Again Harvey recognizes that speculation is a necessary feature of capitalist investment and that investors will always seek to weigh risks against potential gains. What is key to urban entrepreneurialism is that the risks are now commonly borne by local public agencies. Again, Harvey is keen to distinguish how the assumption and distribution of risk marks a break from earlier phases of entrepreneurial activity. This second aspect of urban entrepreneurialism provides the focus for a significant amount of recent research. A number of studies have sought to describe and examine the different vehicles and schemes through which public agencies have encumbered the risks of speculative investment. These include the myriad ways in which local states and state agencies abate or defer the collection of taxes and revenues. This work, in turn, dovetails with a broad research tradition in urban studies examining the fiscal health of local and municipal government. The novelty of urban entrepreneurialism rests not in the presence of such risks – New York City in 1975 and Cleveland in 1976 serve as two high-profile cases of municipal bankruptcy – but in the proactive way in which local governments have assumed the risks associated with speculating on the future of the city.

Work on the fiscal side of entrepreneurial activities includes studies of the increasing use of property and other tax abatements that seek to encourage capital investment. The use of such incentives has a long history in the United States but the period since 1970 has witnessed their proliferation at the urban scale. While the onset of recessionary conditions in 2008 might be seen to harbor greater caution in the use of such programs, many cities and local governments are now faced with the fiscal consequences of speculating on future growth as developments are abandoned or delayed as a consequence of recessionary conditions. Property tax abatements were an early measure designed to encourage urban investment, although the complexity of financial measures has increased significantly over the past four decades. One particularly widespread vehicle currently employed in the United States is tax-increment financing in which projected increased taxes from urban development are used to fund capital improvements and other expenses that enable and accompany the planned development (Johnson and Man, 2001). The reliance on the projection of estimated future revenues brings into sharp relief the speculative nature of such schemes.

Harvey's third characteristic of urban entrepreneurialism – and perhaps the least well specified of the three – reflects his long-standing concern with the geographies of the activities that underpin the changing form of the capitalist city. Harvey argues that the effects of entrepreneurial activities can no longer be readily conflated with the territories in which those initiatives and projects are located. Baltimore's Inner Harbor development – in many ways a classic flagship urban entrepreneurial project – had economic, political, and cultural significance that extended well beyond the residents immediately impacted by its development. In this aspect of Harvey's argument, one can perhaps begin to trace the influence of a now burgeoning set of authors and studies highlighting the fragmented nature of the contemporary city (Graham and Marvin, 2001).

Urban Entrepreneurial Strategy

The three distinguishing features of urban entrepreneurialism provide a valuable means of unpacking changes in how cities are governed. While each provides a window on the contemporary city, it is the historical confluence of the three that marks a distinctive change in how one might best theorize and study the city. One of urban entrepreneurialism's particular strengths is its ability to encompass a wide range of different activities undertaken by place-based coalitions seeking to promote the city and their particular stakes within it. Mediating between the broad concept and the details of particular cities, Harvey identifies four options or strategies that provide a template for examining how particular coalitions of interest seek to place a city within broader economic and political structures. In this way, the concept has considerable flexibility and cleverly avoids conflating urban entrepreneurialism with any one particular strategy or policy. What counts as urban entrepreneurialism depends on the interests engaged in urban governance, the nature of the relationship among them, and the general character of the activities pursued. In these terms, the claims made by Harvey can be examined across a diversity of different contexts.

The first option, and arguably the broadest of the four, involves positioning the city to exploit particular advantages in the global division of labor for the production of goods and services. This opens up a wealth of different competitive

possibilities from a strategy of commodity production based on low-cost labor to the mobilization of key labor skills and talents attached to particular niche sectors. The possibilities here are multiple and the framework encourages us to recognize the politics involved in assembling local economic development strategies. In the US context, emphasizing the low cost of industrial labor has commonly been allied to a series of initiatives designed to inhibit the presence of unions and ensure an adequate and reliable supply of labor. Yet competition on the basis of labor costs is only one of a number of different possible strategies and, in certain instances, cities have sought to attract industry and economic activity that rests on professional, skilled, and relatively well-paid labor. The competition between cities to host creative industries and the employment associated with them is a popular example of competition on the basis of labor skills rather than labor costs. Similarly, the rash of initiatives to construct science, technology, and research parks commonly plays to the theme of attracting and retaining skilled labor.

The second pathway is to seek improvement of the city's place within the spatial division of consumption. The strategy is similarly geared to the attraction of investment and revenue into the locality. Activities that fall into this category include the promotion of cultural events and facilities to attract tourists and tourist spending. This is often accompanied by the construction or redevelopment of public facilities including art galleries, museums, concert halls, and aquariums. The overall strategy commonly involves a cluster of facilities in the form of a cultural district or neighborhood designed to attract visitors to the city. Significant capital investment whether in the form of sporting venues or convention centers can also form part of the strategy designed to position the city as a destination for visitors and visitor spending. Indeed, urban entrepreneurialism usually entails far more than the simple reimaging or rebranding of the city through the use of promotional materials. The consumption-based model covers a wide variety of different activities and pathways. In the European context, Barcelona tends to be heralded as a benchmark of urban development centered on cultural activities (Blanco, 2009). Yet the shift to entrepreneurialism is a widespread and general feature of the contemporary period and the competition surrounding the award of major cultural and sporting events provides further evidence of the growing intensity of consumption-based interurban competition.

A third strategy involves enhancing the position of the city within the spatial division of command and control functions. Here, Harvey links urban entrepreneurialism to the then burgeoning interest in global cities and their place in marshalling the flows of commodities, capital, and information that make up the global economy (Sassen, 1991). For cities such as New York, London, and Chicago, their key role as critical nodes within global financial markets and networks is a position deemed to require a constant stream of initiatives and improvements to the social and physical infrastructures that sustain their place within the wider flows of the global economy. Whether in the form of the new office space for financial services – such as those housed in the London docklands – or the role of airport hubs in encouraging the relocation of head offices – such as Boeing's move from Seattle to Chicago – the interests at the core of urban entrepreneurialism seek to protect and enhance the city's position in orchestrating the flows that connect the global economy.

While the first three strategies are largely concerned with the city's economic position, the fourth is very much centered on investment managed by the state. Harvey argues that urban entrepreneurialism can assume a concern with the redistribution of surpluses as cities seek to draw upon the resources and revenues collected and spent by higher tiers of government. The competition among cities and local governments for state facilities – whether in the form of university campuses, government offices, or even penal facilities – heralds the fourth strategy through which cities seek to promote their position within wider networks. In the United States, a concern with the geographic distribution of military and military-industrial facilities provides a particularly acute example of the competition for national state spending, albeit one that commonly encompasses actors and interests beyond those coincident with the city.

The menu of options from which local coalitions can draw points to the range of activities and initiatives compatible with the shift to urban entrepreneurialism. Furthermore, those invested in the city might seek to pursue more than one particular strategy. Indeed, the proactive role of urban-based interests in determining the strategies and policies pursued by local agencies provides grist to the mill for the study of urban politics and a sizable body of work reflects how this has played out in a variety of urban contexts (Hall and Hubbard, 1998). Through the link between territorial interests and the strategies they pursue, there are clear connections between the issues raised in Harvey's account and the broad and influential literature on urban growth coalitions and urban regimes. For Logan and Molotch (1987), the glue that holds together the otherwise potentially disparate interests animating the local coalition is the pursuit of growth. Yet how growth is manifest for Logan and Molotch is very largely reduced to the suburbanization of the city and the transformation of green space into urban form. In this formulation, property developers and land speculators lie at the heart of the growth coalition. Urban entrepreneurialism, by contrast, accommodates a much wider set of avenues through which ruling interests might seek to realize their stake in the development of the city. Accordingly, the concept has wide resonance.

Urban Entrepreneurialism in Context

Work adopting regime theory and the growth coalition shares urban entrepreneurialism's concern with the proactive role of local interests in seeking to manage the agenda of urban governance. Where urban entrepreneurialism differs from these concepts is in the emphasis placed on the constraints that shape both the practices of local elites and the extent to which entrepreneurial activities are successfully realized. In Harvey's formulation, activities within any one city are conditioned and shaped by the activities taking place elsewhere. The argument works at two levels. First, urban entrepreneurialism represents a general shift in how cities are managed and the new phase is marked by the replication of similar strategies and initiatives

across multiple urban contexts (Wood, 1996). The promotion of an arts and entertainment district becomes a more or less universal feature of the urban landscape. The recent policy mobilities literature is explicitly concerned with how urban initiatives and policies proliferate, emphasizing how they develop in one particular context and are then mobilized and deployed elsewhere (McCann and Ward, 2011). Such work provides significant insight into how the practices encompassed by urban entrepreneurialism – from the development of cultural districts to the pursuit of city-wide visions – seem to diffuse so quickly. For Harvey, the "serial reproduction of similar forms of urban redevelopment" (1989: p. 10) is a hallmark of the turn to entrepreneurialism.

At a second level, the constraints inherent in urban entrepreneurialism arise from the manner in which interurban competition for investment is structured or, in short, the rules that determine which strategies are successful and which are not. For Harvey, the suite of entrepreneurial activities is subject to the discipline of capitalist competition such that policies other than those serving the general interests of capital are always liable to be undermined. Harvey is less clear on how the discipline of competition is achieved in practice and the rather pessimistic view of the prospects of alternative strategies is moderated in his more recent work. In examining the discipline imposed on entrepreneurial activities, the work of Jason Hackworth on the neoliberal city is particularly helpful (Hackworth, 2007). For Hackworth, critical mediators in the interurban competition for investment are the bonding agencies that evaluate the extent to which local public authorities are capable of repaying their long-term debt. As Hackworth puts it, "the connection that cities have with capital markets is determined more than ever by the neoliberal standards enforced by rating agencies" (Hackworth, 2007: p. 33). For Hackworth, it is no coincidence that the turn to entrepreneurialism coincides with the growing dependence of cities on municipal debt to cover their spending on the provision of social services and capital infrastructure.

While the growth coalition and the urban regime frameworks tend to bracket out the broader economic and political forces that shape urban politics, urban entrepreneurialism encourages us to examine how the initiatives registered at the urban scale articulate with the broader changes characterizing the capitalist space economy. Rather than isolating the urban as a discrete political arena or reducing urban change to 'the effects' of broader economic forces, the initiatives and pressures at the core of entrepreneurialism are seen to have an important role in shaping the contours of capitalist development. In preparing the city for external investment, urban entrepreneurialism serves to encourage further rounds of place-based competition as entrepreneurial activities lubricate the flows of mobile investment that produce change in the global political economic landscape. Consequently, the urban is coupled to changes taking place across a range of geographical scales and the transition to urban entrepreneurialism can be read as integral to increasing place-based competition rather than the residual effect of the increasing mobility of capital. Indeed, central to Harvey's account of urban politics is not the mobility the capital favored by certain schools of thought but rather the endemic tension between the value locked in the immobile or fixed material and social infrastructures that make up the city and the flows of investment required to unlock that value and realize profit. The tension between fixity and mobility is similarly at the core of Cox and Mair's argument concerning the local dependence or geographic fixity of certain agents and their efforts to attract the flows of investment necessary to secure the economic health of the locality (Cox and Mair, 1988). Furthermore, the mobilization of place-based identity engendered by interurban competition provides a means of uniting social interests and groups and thus displacing the social and spatial divisions that Harvey and others see as endemic to the capitalist city.

While Harvey's argument has been widely cited, work deploying the concept of urban entrepreneurialism has proceeded unevenly. A significant body of recent work centers on the production of the facilities, landscapes, and images associated with the promotion of the entrepreneurial city. Short et al. provide an intriguing case study of how political and economic interests in Syracuse, New York, sought to rebrand the city from one marked by its association with an industrial past to a new image playing to the city's role as a destination for conference goers and retail consumers (Short et al., 1993). This is not to suggest that place marketing should be conflated with the turn to entrepreneurialism as the work of Gold and Ward (1994) on the history of place promotion clearly indicates (see also Kearns and Philo, 1993). Harvey's own work on the Baltimore Inner Harbor has also provided a model for subsequent work examining how 'flagship' projects – such as convention centers, museums, or cultural districts – mark the development of increasingly entrepreneurial strategies (Harvey, 2001). The shift to entrepreneurialism has also provided the context for a range of studies that have sought to detail how entrepreneurial strategies and the interests that promote them have displaced traditional arrangements for managing the city (Boyle and Hughes, 1994).

Unpacking the business interests that animate the drive to entrepreneurialism is a second area that has garnered attention. In urban studies, the term 'business community' is commonly taken as sufficient to capture the range of private interests and agents that have a stake in the development of the city. Harvey's account encourages a more nuanced view and scholars in the United States and Britain have sought to examine how different fractions of the business class have engaged with and encouraged the shift to entrepreneurial strategies (North et al., 2001; Valler, 1996; Rogerson and Boyle, 1998). How the practice of creating and mobilizing local business interests works in different national contexts raises the more general issue of the portability of the concept of urban entrepreneurialism and the arguments that underpin it. Scholars working in Great Britain have suggested that the framework tends to overplay the capacity of local business interests to bring about change. Peck and Tickell's work on Manchester provides a careful and thorough investigation of the weakness of the Manchester business community, reflecting both the development of national and increasingly transnational capital on the one hand and the autonomy of local government from business interests on the other (Peck and Tickell, 1995). The development of radical local authorities in Liverpool, Sheffield, London, and elsewhere

during the 1980s is witness to the strength of cross-national differences in the nature and role of the local state and, in particular, its relation to local business interests.

However, there are a number of areas in which work on urban entrepreneurialism remains underdeveloped. Rarely have studies examined how local residents have experienced the impact of entrepreneurial initiatives and how the distribution of costs and benefits has played out in particular cities. MacLeod's study of Glasgow provides a rare exception and examines how the repositioning of the industrial city has been accompanied by the marginalization of its least powerful residents (MacLeod, 2002). Yet how residents come to identify with the projects, ideas, and policies that underpin entrepreneurial strategies remains a question for further work (Hall and Hubbard, 1998).

While the concept of urban entrepreneurialism served to capture a number of different trends in the nature and purpose of governing the capitalist city, there has commonly been a significant gap between the concept – pitched at a relatively high level of abstraction – and the concrete changes examined in the study of the city. Urban entrepreneurialism has tended to provide a context for study rather than a set of propositions that serve as research questions or themes that lend themselves to empirical investigation. Studies have commonly sought to examine how urban entrepreneurialism plays out in a particular case rather than using a particular case or set of cases to examine the conceptual limits of the arguments. Furthermore, much of the work to this point has centered on cases drawn from North America and Western Europe, which raises a host of interesting questions about the insights that might (or might not) be gained from deploying the concept in a range of quite different settings.

Since its original formulation in 1989, additional concepts have come to frame the study of the capitalist city. Neoliberalism and the neoliberal city are, arguably, the most prominent and it is this concept that has displaced urban entrepreneurialism as the favored theme for radical urban studies. Harvey has made a significant contribution to understanding neoliberalism, although these arguments are commonly pitched at the global scale rather than focused specifically on its implications for urban form and how cities are governed (Harvey, 2005). Many of the themes raised in relation to neoliberalism clearly have a bearing on cities and the freedom of trade, the liberalization and deregulation of markets and the veneration of the market relative to the state are each consistent with the turn to urban entrepreneurialism and entrepreneurial governance. Moreover, the continued resonance of urban entrepreneurialism might be seen to rest in its capacity to link the latest phase of capitalist development with the profound set of changes that have characterized how cities are governed.

Abstract

Urban development processes are greatly affected by structural transformation of societies. Over the past decade, societies have witnessed changes that were unprecedented in recent history: the collapse of political and economic systems, new integration policies, globalization of the economy and the decline of the nation-state, mass migration, governmental retrenchment, and social restructuring. Structural changes in societies manifest themselves distinctly in urban areas and every generation needs to engage in the discourse on a country's built politics, the sustainability of urban form and design, and the ecological footprint of major cities and suburban areas. Urban geography deals with the analysis of the complex dimensions of urban social, economic, cultural, and political processes, patterns, and structures and urban planning processes to build up or retain local comparative advantages, while retaining cities as livable urban places and securing their sound social and environmental development for future generations. This article describes the conceptual and methodological approaches and the long-term prospects of urban geography.

Introduction

For the first time in human history, the majority of the world's population lives in cities. The megacities of low-income countries are subject to rapid growth and as a result are increasingly difficult to govern. For megacities in developing countries problems arise from their ever-growing populations and the fragmentation of cities with parts of the urban economy partially integrated into the world economy and parts being left out even of national development. Their challenge is to accelerate economic and balanced, sustainable development in order to reduce the potential of violent conflict and to support peace processes. Urban/metropolitan areas in highly industrialized nations are likewise facing challenges, including increased intraurban competition for investments and tax payers', and to increase their capacity to protect and strengthen collective security.

Theoretically informed social science research is necessary to monitor trends of urban development, to provide basic information for the optimization of local strengths and to meet local needs, and for urban planning that respects collective decisions, increased competition, modern urban structures, and the individual 'feeling' of a city. Social science research defines and analyzes the generators of urban development and brings to light basic information about urban structures and processes, perceptions, for example, of inner city problem areas, and the attractiveness of cities. This is where urban geography has an important role to play.

Urban Geography: Tasks and Approaches to a Social Science Discipline

The Scope of Urban Geography

Urban geography deals with the analysis, explanation, and prognosis of urban forms, urban social fabric, and economic structures and functions. Questions encompass economic, political, social, and ecosystem geography in their urban contexts at various scales, from the macroscale of the urban system to the mesoscale of metropolitan functional urban areas to the microscale of urban neighborhoods, streets, and even individual households. The scientific results of urban research increasingly serve as a basis for decisions on public investment, allocation of resources, and urban development planning. Urban research can be broken down into interurban (system of cities) and intraurban analyses that address the processes going on in cities (*see* Cities: Internal Structure). Conceptual approaches pertain to urban form and urban morphology, the urban social fabric and economic structures, and urban development and urban policy.

Urban Form and Urban Morphology

This approach deals with analysis of the built environment. Changes in urban morphology, including historic/heritage preservation, the creative reuse or restoration of landmark buildings, and urban revitalization, have gained importance in recent years for at least the following two reasons. (1) The built heritage of cities displays layers of significance and narratives that bridge the past with the present. As heritage properties have symbolic, esthetic, and emotive values, measures to protect heritage planning can improve a city's attractiveness for residents and investors and hence, the city's fiscal base. (2) Urban morphology has been linked to national defense strategies as was the case during World War II and the Cold War when dispersed urban development became an integral part of national policy in the United States (Augur, 1948).

Urban form and urban morphology have also been taken up in Neo-Marxian/Neo-Marxist urban geography. The regulationist school, for example, links power structures to the functioning of urban regimes. According to this school of thought, investment in modern urban centers is a means of accumulating capital at the cost of other urban subareas, a process accompanied by policies of neglect and disinvestment. Social and welfare disparities as are manifest in differing morphologies across urban space have thus become another major area of urban research.

Urban Function and Urban Social Structure

Analysis of Urban Land Use Development, Urban Functions, and Specializations

Specialized economic activities seek locations with the greatest competitive advantage. This approach helps to understand urban land use development and to determine those land use patterns that most competitively provide basic support for the city. The internal structures of specialized urban functions (wholesale, retail, service activity, etc.) within the city are points of focus. On the microscale of the city, the analysis of central business districts and neighborhood business have received priority (Weaver and Duerksen, 1977; Alperovich, 1982; Mallet, 1994; Briffault, 1999; Ward, 2007; Duranton and Puga, 2005). On the meso- and macroscales of urban systems analysis, the degree of specialization in and between cities is considered the base for identifying a city's market potentials, strengths, and niches within a regional or national hierarchy of cities. Results from urban systems research on urban specializations have found their way into policy analysis of regions that are in need of economic, social, and territorial cohesion. Here, public funds fostering place-based policies are channeled into places best able to contribute to the sustainable and balanced development, as identified by urban systems research. This, for example, was the case in Germany after reunification (Spangenberg, 2008; Bundesinstitut für Bau-, Stadt- und Raumforschung, 2012).

Empirical Examination of Factors Organizing Space and Megalopolitan Structure

This approach deals with the metropolis as a changing configuration and the processes by which metropolitan areas grow and expand beyond their rigid corporate limits. Studies of metropolitan patterning examine the functional differentiation of suburbs, the interrelation of the city and its surrounding area through economic linkages and commuting, and the way metropolitan communities reorganize themselves into supra-metropolitan functional urban areas (Antikainen, 2005; Perlik et al., 2001; Anthrop, 2004). The development of megacities, the increasing functional specialization of metropolitan centers and communities, and their growing interdependency are key research issues, as is the general theme of urban governance of such larger functional urban entities that extend beyond administrative borders (Coombes et al., 1982; Van den Berg and Braun, 1999; Meijers 2005).

Urban Social Geography and the Factorial Ecology of Cities, Social Status Differentiation, and Segregation

Urban areas are highly differentiated complex systems (see also Cities: Internal Structure in this encyclopedia). These approaches deal with urban subareas, urban subpopulations, social and economic characteristics of urban neighborhoods, the social patterning of local residents by race, ethnicity and class, and the behavior of subpopulations as a function of their social group, race, and class, or as mediated by the characteristics of the neighborhood, urban subarea, and the urban system. This approach has recently become more important given the tendencies for growing social exclusion of individuals, household, groups, and communities with respect to education, equal employment opportunities, cultural and gender norms, incomes, occupational status, and social networks based on race, gender, class, origin, or religion, and given new policies against social exclusion. Combatting such tendencies, for example, has been integrated into the European Union (EU) Treaty of Maastricht and related European economic development programs, and it is by means of geographic social science research that one can track progress or stagnation in this regard.

Urban subarea characteristics and urban social and spatial differentiation are commonly analyzed using factorial ecology. This term refers to various statistical approaches using factor analytic methods. Small area analyses with a limited set of variables grounded in social theory is common. Factor analysis, on the other hand, depends on a large number of variables that are then reduced in an exploratory way to essential properties of a particular phenomenon of urban subareas or urban space. It determines urban subareas according to common social characteristics or in terms of households or individuals with common characteristics.

The urban ecologist or social geographer does not focus on spatial differentiation per se. Rather, the urban geographer studies such patterns with a view of uncovering the social, political, economic, or cultural processes that may be responsible for these patterns. Residential segregation of different social status groups, for example, occurs in many different cultural settings. In increasingly multicultural societies, patterns of differentiation among social groups and neighborhoods and their particular spatial geometry are extremely complex. Factorial ecological investigations help to monitor processes of social distance as reflected in the degree of physical distance and residential separation. Of note in this context is a major EU research program called ESPON – European Observation Network, Territorial Development and Cohesion. This applied research program provides pan-European geographic information systems (GIS)-based and social science-based evidence and knowledge about European territorial structures, trends, perspectives, and policy impacts. The research enables comparisons among regions and cities with the overall goal to tailor result-oriented policy toward promoting economic prosperity, competitiveness, territorial cooperation, social cohesion, and more sustainable development throughout the EU.

Perception of the Urban Environment

This approach sees age- and social-status-related perceptions of the urban environment, personal activity radius, and spatial behavior as related variables. Individual perceptions of reality affect spatial behavior, be it shopping trips or intraurban migration. Different groups such as the elderly, the youth, and the poor have distinct ranges of activities and different patterns of spatial behavior. Market research utilizes the results of studies on the perception of the urban environment and spatial behavior. At the microscale of individual urban geography, studies concentrate on activities that a person does regularly and places that are visited regularly, i.e., daily or weekly. These may be analyzed using the methods of time geography and indicate an individual's capabilities to overcome distance by means of mobility and communication. At the macroscale, the collective spatial behavior of social groups and the spatial

geometries of social group behavior are the focus. Decisions regarding distances between shopping centers and other central urban functions, for example, make use of empirical findings of collective spatial behaviors.

Perceptual geographic urban analysis upholds the theory that spatial behavior, like intraurban migration or shopping and recreational activity, is often limited to a closed field of perception and reference, and it is affected by personal spatial evaluation. The overall image of a city from the point of view of commercial interests is affected by 'soft' locational factors (e.g., amenities, attractiveness of the urban environment, social and demographic processes in the city, or business climate). Image analysis can contribute significantly toward finding reasons for the exodus of population, companies and enterprises, or disinvestment. Moreover, measures for the improvement of a negative city image or for instigating desired development can be recommended. Image analysis, therefore, has become an important instrument and base for (re)defining strategies for the marketing and branding of cities and urban regions.

Urban Development

The Analysis of Urban Development and Urban Morphology as Related to Historical, Political, and Geographic Peculiarities

This approach that dates to the 1930s and was rooted in the analysis of European cities deals in particular with the development dynamics of the city and the determinants of that development. Urban development analysis takes the positive consequences (e.g., concentration of social and economic performance, importance as center of innovation/innovation hub) and negative consequences of development (e.g., environmental problems or urban blight) into consideration. Today, this approach offers important insights for the political, economic, and social components of urban development planning.

Urban Cultural Geography, Intercultural Comparison of Cities, and Urbanism

This approach emphasizes the historical and cultural context of cities. Processes of urbanization and the current physical urban structures of cities, including their inner differentiation, are assumed to be products of a series of sociopolitical systems. In cultural genetic urban geography (see Section Culture Type of Cities below), persistent historical urban structures are identified according to the appropriate historical social system and cultural sphere of influence. Because society changes faster than do physical urban structures, linking historical patterns in the urban fabric with historical social systems is a major focus of research in cultural genetic urban geography.

Culture Type of Cities

This research focuses on culture-specific differences in urbanization and urban structure that were created in the course of historical development. The physical structure of the city and the differentiation of urban quarters are seen as related to the value system and demands of a dominant culture. Commonly, such cultural imprints are evident in the central parts of many modern cities. Proponents of this approach hold, for example, that cultures and historic contingencies have shaped cities differently according to the predominant cultural values of the respective society and epoch. Cities in all cultures have reflected the visions, fundamental beliefs, and ideological orientation of their founders and of successive generations.

In today's competitive globalized and technically oriented world, historical built heritage as well as cultural and spiritual norms provide an important record of human achievement. As pointed out by Gospodini (2004), the constructed landscape narrative serves as a place identity generator. Being able to read historical urban landscapes may make unfamiliar environments familiar and overcome xenophobia.

Postmodern Urbanism

Postmodern urbanism aimed to provide a consolidated body of theory challenging the Chicago School: The so-called Los Angeles School utilized Marxist and poststructuralist theories to interpret sociospatial differences in late-capitalist, globalizing cities (Dear, 2000, 2003, 2005; Dear and Dahmann, 2008). Los Angeles, deemed to show exceptions from established urban theory, became the laboratory for postmodern urban studies. The *gestalt* of the late-twentieth-century city no longer possessed concentric order or homogenous sectors according to postmodernists. Rather, postmodernists saw a mosaic of fragmentation, with poverty landscapes and spectacular centers of symbolic and commercial significance, representing the activity of global capital. Such centers could be in the center or peripheral nodes. These new urban developments were seen as dramatic and polarizing. Spectacular urban design elements were interpreted as manifestations of fierce global competition and necessary 'unique selling points' that could distinguish one city from another in the competition for global capital. To capture both the driving process and results of such urbanization, many concepts have been put forth, including *world city*, *dual city*, *hybrid city*, *cyber city*, *fragmented urbanism*, *edge cities*, and *fortress urbanism*.

Despite its claim to novelty, postmodern urbanism may be understood as a variation of the theme of culture-specific urban development: Whereas in former times the combination of mercantile feudal systems and ecclesiastic power and wealth shaped cities, creating monumental worldly and church architecture but leaving entire city quarters neglected, in contemporary society, the combination of laissez-faire capitalism, big corporations, and government devolution shapes cities. Now, as then, hegemony and capital are driving forces of polarized urban development. Postmodern urbanists drew attention to problems of fragmentation and to the need to explore them more intensively and make them a political issue.

Urban Policy Analysis

Globalization and Urban Policy

Cities are social systems in space that react to the following local and supralocal developments:

- Increasing competition among metropolitan areas as a result of globalizing economies and cultures.
- Deregulation and separation of social politics from trade and industrial politics.

- Economic and political integration as well as political and environmental crises that initiate migration flows.
- Change of societal values and pluralism of lifestyles.

Global economic restructuring, increased competition among cities, and the decline of the welfare state force cities to pursue entrepreneurial urban development strategies. These may include economic incentives, the promotion of investments or megaprojects to increase urban attractiveness, and a focus on growth rather than redistributive urban development. Also, public–private partnerships or urban regimes that emphasize private sector planning have emerged.

Urban regimes follow different approaches to development; some implicitly exclude or include social policies as part of their overall strategy, with differing impacts on long-term development processes. For an individual city, analyzing the interrelationships among urban policy, urban development, and the changing geometries of segregation helps to understand how and why planning may unintentionally influence social and spatial polarization. Given the adoption of Western urban policy and planning models in other countries, it is important to understand social, spatial, and economic implications of each type of policy for urban development in different cultural settings.

Government Devolution: The State and Local Response

In a national urban system, the relationship between national/federal urban policy and local policy and local urban development is of interest to urban geographers: what happens in cities when federal policies change? Recently, financial responsibility has shifted away from national governments toward state and local governments. Noteworthy, however, is the co-occurring tendency since the early twenty-first century for central governments to assume extensive responsibility for funding issues deemed vital to national interests, with impacts on every household locally.

The trend toward government devolution with respect to issues considered local has been observed particularly in the US and Western European federal systems; it has prompted concern that social problems may worsen if the federal/national role of counterbalancing unfavorable social and economic developments is restricted. While federal/national policies may at first glance adversely affect areas of concentrated poverty, one must look at local policies and responses to Federal/national policy to achieve balanced view of long-term adjustments and trends in societal development.

Policy-oriented urban geography studies the problems and potentials of local planning responses to current problems of urbanism and federal and state policies, such as social/economic disparities, caused by policies at various levels. Research on restoring inner city neighborhoods in the United States reveals examples of innovative community concern expressed by public and private sectors with the potential to counterbalance public sector devolvement to some extent. European nations, among others, have developed interesting local policy mechanisms to deal with the ills and imbalances of society manifest in urban areas (Bundesministerium für Verkehr, Bau und Stadtentwicklung, 2012, 2013).

Methods in Urban Geography

Conceptual approaches focus mainly on two perspectives.

- Those related to urban space and urban subarea characteristics, the basic dimensions of city patterning and the determinants and processes behind changing structural characteristics of urban space over time.
- Those related to people in urban space, e.g., individual and collective spatial behavior (for example, shopping trips, commuting, daily activity ranges), people's perceptions of urban space, and planning processes or projects.

Concomitantly, two major, complementary methodological approaches characterize urban research: (1) empirical regional/urban subarea analysis and (2) empirical social science, particularly survey methods.

Methods of Empirical Regional/Urban Subarea Analysis – Urban Social Monitoring

Societal developments manifest in urban space and are reflected in structural characteristics of urban subareas. Urban geographers analyze the aerial structure of urban communities in terms of aerial attributes. The methods correspond to those found in regional geography in so far as they help to delineate and observe structural changes of agglomerations, city centers/cores, urban expansion, and suburban areas. Within the city, research units are districts and neighborhoods as well as other 'official' spatial units, whether defined for planning, political, or statistical purposes. Urban subareas may be of any scale; census tracts and smaller census units are commonly used as statistical reference areas to characterize the increasing differentiation of urban social milieus.

Urban subarea analysis enables *urban social monitoring*: documenting and analyzing detailed socioeconomic structural patterns and processes of change. Complex spatial processes are broken down into individual components. The following three statistical approaches are important. (1) For *descriptive purposes*, methods include computer-assisted cartography and the refined cartographic and analytic methods enabled by GIS. These produce unidimensional or multidimensional maps of social, demographic, or other phenomena as differentiated in urban space. GIS, of course, is also suited for the establishment of a long-term statistical–cartographic database, which can be periodically updated. Such a database simplifies thematic longitudinal onsite analysis of the target urban region with regard to social, economic, and demographic processes and forecasts. (2) In a more exploratory sense, *factorial ecological investigations* use a number of multivariate descriptive statistical techniques (the methods of factor analysis) to identify the essential characteristics that differentiate one urban subarea from another. *Cluster analyses* subsequently performed on factor-analyzed urban subareas can help identify groups of subareas with common patterns of variability. (3) In order to understand the determinants of such patterns, one may combine descriptive and analytical statistical techniques. Factor scores from factorial analyses may, for example, be used as input data in *multiple regression*

analyses that relate these aggregate characteristics to explanatory variables.

Social monitoring of urban subarea characteristics over time enables evaluation of current structural changes: urban geography relies on statistical data collected by public and private institutions or public welfare organizations. As the data reflects institutional norms and goals, analysts have no influence on the survey method or the aggregation and systematization of the indicators. Consequently, theoretically informed urban research is limited by the quality of these (secondary) data sources, which is continually improving.

Survey Methods – Empirical Social Science Research

Survey research methods are needed to analyze activity systems/patterns of individuals or households, as well as preferences, felt needs, perceived quality of the urban environment, and residential behavior in specific urban contexts. Survey research methods in social geography concentrate on the *interrelationship/correlation between spaces and social group behavioral patterns*, designation and appraisal, as well as group perception and evaluation of spaces. An *advantage* of incorporating surveys early in the research process is the ability to identify important issues that are not addressed with official statistics.

The Contribution of Empirical Urban Research

In sum, research questions in urban geography address different sets of issues:

- the physical attributes of spaces or indicators of their functional interconnection
- immaterial aspects (spatial perception or space-related activity)
- both of these or
- aspects of spatial change that result from the interaction between immaterial and physical elements (e.g., the physical results of political visions for the urban area and the consequent measures, or sociospatial disparities caused by power relations in society)

Studies of objective reality (e.g., sociogeographic structural analysis) use data that reflect numerically definable spatial characteristics that can be utilized in factorial analysis (as opposed to subjectively perceived spatial attributes). This data is mostly found in official statistical material, published and unpublished, the basis of which are extensive censuses (e.g., of population) or surveys (e.g., of enterprises). Personal, small-scale, and tailored surveys are necessary if the time lapse between official censuses is too great or if certain key data elements are missing (e.g., building conditions in different neighborhoods). However, if the research focus concerns the activity patterns of individuals and groups, interviews are necessary if spatially related behavior, socioeconomic background, and possible consequences of behavioral patterns are to be dealt with. Between factorial ecology and survey methods, only the data sources and the scale of the evaluation differ. Even though the goals may vary, the *basic principle* of *preparing and evaluating* official or specifically collected social data from survey research in a descriptive and/or quantitative analytical manner stays the same.

Key Features of Urban Geography

The standing of urban geography within the social sciences draws on three elements that other disciplines dealing with urbanism do not share to the same extent.

Combination of Conceptual and Methodological Capabilities

- Empirically and theoretically informed research from an integrated perspective.
- Relevance to society.
- Diversity of urban research topics in social, economic, and environmental fields, among others. The range of *urban research topics* includes, for example:
  - Changing patterns of residential segregation, the persistence of urban poverty, the rise of gated communities, housing and urban labor market developments.
  - Urban environmental quality, questions of environmental racism.
  - Functional interrelatedness of cities and their suburban areas.
  - The territorial embeddedness of global impacts.
  - Local policy responses to supralocal trends.
  - Entrepreneurial urban policy and microscale urban social development.
  - Cross-cultural urban development.
  - Urban systems development.

Specific Methodological Competencies and Diversity of Analytical Responses

- Empirical research: primary survey methods, such as monitoring, mapping, or field surveys.
- Statistics: drawing conclusions about research questions/hypotheses via processing spatial primary data and official statistical secondary data.
- Cartography: tool for working with and presenting spatially differentiated phenomena.
- Remote sensing: interpretation of aerial photos and satellite photos as an important source of information.
- Using GIS to present and analyze data and developments in space.

Decoding Highly Complex Encrypted Urban Social Landscapes

Urban geographic thought ranges from notions of culturally shaped cities to cities formed by modern societies and cities having lost their character as a result of postmodern societal development or the culture of globalism. Concomitantly, urban analysis has proliferated to be able to track each facet of urban development as it was conceptualized and postulated to exist. The cumulative analytical expertise is shown in Table 1.

Conclusions

Global economic restructuring, political change, government devolution, and social restructuring alter urban and regional

Table 1 Urban geographic analysis: spatial reference levels and research emphases

	Systems, spatial reference levels	*Research emphasis (examples)*
Interurban systems	**Global/international levels**	● Worldwide or international urbanization ● Worldwide distribution of megacities, global cities, etc. ● Types of cities/culture type of cities (comparative perspective) ● Cities in industrial and developing countries
	National, regional, and interregional levels	● Regional types of cities
	Intraregional level including functional urban regions and large metropolitan areas	● Development of conurbations ● Relocation of businesses/corporate headquarters, administrative authorities ● Mobility, including commuters, retail activities, leisure related ● Central place systems, urban networks, and urban systems
Intraurban systems	**Entire city or municipality**	● Urban development and structure ● Inner city centers or system of centers ● Shopping centers at the urban fringe vs inner city retail centers ● Suburbanization processes (population, commerce, and industry) ● Sociospatial segregation/fragmentation ● Inner city mobility/leisure and shopping behavior ● Urban image and city marketing ● Urban traffic systems (public transportation)
	Mesoscale urban areas (city quarters, neighborhoods)	● Living conditions in neighborhoods ● Housing market and residential location
	Microlevel urban areas (retail locations, street sections)	● Social structure, social problems in inner cities and neighborhoods ● City functions, central business districts and commercial streets ● Inner city structure, commercial developments ● Urban form, built environment ● Urban renewal, neighborhood rehabilitation and planning, pre-analysis and accompanying studies ● Environmental pollution (noise, emissions, fine dust, etc.)

Based on Heineberg, H., 2014. Stadtgeographie. Grundriss Allgemeine Geographie, fourth ed. Schöningh, UTB, Paderborn, p. 23.

fortunes and give rise to new sociospatial patterns of development. Fragmentation, polarization, and new local spatial identities form new urban realities. Formerly prosperous cities may lose their comparative advantage. To retain competitiveness and build up local (endogenous) potentials or to govern uncontrollable cities, new models and modes of planning are being developed. In cities of the Western world, public–private partnerships – coalitions of major local economic and political players – have been outlining/developing and implementing grand visions of development. Many megacities in low-income countries have difficulty coping with the basic infrastructural needs of their populations.

Thus increasingly, in cities worldwide, urban planning and the prevailing urban regime and its orientation and complex interaction with the regional, national, or supranational economic and political systems have a significant effect on the development of a city. In order to deal with contemporary urbanism, decision makers will need to rethink urban processes, structures, and policies. Understanding the city from a systems perspective is required because urban development, form, and social and economic structure are intertwined with the larger society, economy, and politics nationally and internationally. A systems perspective also understands the city as an organism/entity with enormous local capacities and strengths that might successfully counteract the local or regional effects of globalization or other supralocal forces.

Urban geography is a systems-oriented social science discipline with great relevance to interdisciplinary solutions of problems of urbanism and urban and urbanizing areas. The systems perspective, the methodical skills required, and the variety of theories and research questions in urban geography make this discipline well suited to understand and deal with problems of contemporary urbanism.

Abstract

Models can perform the dual functions of organizing knowledge of how urban systems work and grow, and providing support for analyzing policy and planning proposals. Modern urban modeling has progressed substantially in the last 50 years, as a result of extensive development supported by massive data collection and growing computing power. Much of the development has been impelled by the needs of transportation analysis, but land use or locational modeling has advanced well beyond initially fragmented and descriptive theories. The major difficulty arises out the underlying importance of resource allocation, which is influenced by complex behavioral patterns and requires an interdisciplinary approach. These behaviors are defined too narrowly in purely economic models, and too descriptively in purely observational models of discrete choice. This dichotomy is a major focus of modeling, and is being gradually overcome.

An urban model is a statement about the interrelationships between parts of an urban system, which not only describes these interactions, but makes possible the prediction of the effects of some kinds of changes in the system or in its environment. This is the essence of any scientific theory.

Viewed as a part of a scientific discipline, urban models provide an organizing framework for bringing together many aspects of knowledge about urban life, for testing subsidiary theories, and for identifying gaps in knowledge and guiding future research. Viewed as an aid to professional practice in urban planning or engineering, a model which is operational at a relevant level of detail can provide insights into the future results of new policies, and guidance in their formulation and improvement. To serve these two divergent purposes, a model must be understandable and acceptable to both the scientist and the professional.

Prior to the mid-1950s, many disciplines and professions engaged in disjointed efforts to analyze urban affairs. In Geography and Sociology, there were efforts to achieve an overall view in largely descriptive terms. Examples include Burgess (1927), Hoyt (1939), and Harris and Ullman (1945). Starting in a period of optimism about scientific management, the last 50 years have seen substantial growth in urban modeling, but there are still many imperfections in current models, and obstacles to their filling their dual role. We will try to expose the bare bones of both the progress and the difficulties as they have developed over five decades.

Basic Considerations

An urban metropolitan area comprises a set of organized activities and residential spaces, occupying land and buildings, and using infrastructure. These activities and their containers are at higher densities than their nonurban surroundings, and are more closely connected with each other than with their ambient environment. Their existence and development require the proper functioning of markets or allocation methods for land, for housing, offices, and factories, for labor, and for public and private services, including those of the transport and communications systems which knit these other functions together.

Because of the paramount importance of resource allocation, and the role of real or artificial markets, these interrelationships are largely governed by economic considerations – but with many differences from received economic dogma. There is a division of decision-making between the private and public sectors, necessitated in part by economies of scale and indivisibilities. In the ultimate political sense, economic efficiency is only one of several means to a bundle of humanistic ends. In analyzing behavior, especially that of households and their members, economic forces are greatly influenced and modified by social and psychological ones. Economic analysis depending on equilibrium tendencies ignores or belittles the lags in personal and organizational adjustment to change, and the durability of investment in infrastructure, buildings, and human capital.

There is another and fundamental schism between economic descriptions of 'rational' behavior and the realities of urban life. This divergence has led to two trends in urban modeling which are only now being resolved. In economics, similar actors in similar conditions make similar decisions – people shop at the nearest center, traffic follows the shortest route, and employees seek out the nearest jobs. In reality, some actors make long trips, and roundabout ones (but with diminishing frequency) for the same purposes which might be pursued using shorter and more direct trips. The 'rational' behavior is defined in economic models of optimizing choices, while diverse behavior is described, but not explained, in a number of ways by 'gravity models,' 'entropy maximization,' and 'discrete choice' – three very similar approaches.

By far the most important issue in model development has been this antinomy between an economic view that posits uniform behavior and a humanistic view which posits diversity. These two views underlie different lines of model development, and we will follow their reconciliation, though a recognition of ignorance – a reconciliation which clears the way for the resolution of other but less important difficulties.

Inventing a Paradigmatic Model

In the early 1950s, a number of factors favoring the discovery of a new paradigm in urban modeling came together: on the

ground, through the suburban redirection of American urbanism, and planning and building urban expressways; in technique, through the optimism of instrumental rationalism, seen in Operations Research and Management Science and buttressed by the commercial availability of computers; and in planning, through the widespread influence of the University of Chicago Program. In the middle of the decade, urban land planning began a slow movement in the direction of modeling (see Voorhees, 1959), and the Chicago Area Transportation Study (CATS, 1959) developed an innovative approach, drawing on many sources, which in retrospect must be considered a new paradigm for urban modeling.

A new paradigm in scientific or professional matters involves a framework for studying phenomena and defining their relationships. The importance of such innovation does not imply perfection; implementing and extending the paradigm and overcoming its imperfections may require decades. The essential novelty of this paradigm for analyzing the critical aspects of urban settlement systems extends far beyond transportation itself, and embodies the following elements:

1. Examine the system in all relevant detail, with massive data collection and thorough analysis of user behavior and system responses. (This was done in transportation studies by large-scale sampling of travel behavior and traffic conditions.)
2. Simulate user behavior over the entire system or subsystem, together with the system response, and with feedback in which the system response influences the user behavior. (The simulations in CATS were inventive and completely novel.)
3. Draw heavily on other disciplines that can contribute to the accuracy and realism of the simulations; use exact formulations wherever possible, and implement data management and simulation through computers where this is necessary and relevant. (CATS employed sociologists, planners, economists, engineers, and computer experts – and used computers for its most advanced innovations.)

Similar simulations could be imagined, and indeed have been undertaken, for the housing market, the labor market, the location of economic activity and public services, and the environment. Clearly, these subsystems are mutually interdependent, and in the final analysis their simulations would have to interact.

Despite its seminal influence, the CATS study has often been denied its paradigmatic role because of its shortcomings, most obviously inadequate attention to transit and failure to take into account the reaction of land uses to transportation. It shares many other problems with land-use modeling, as we will see in exploring them. It also embodied the schism between economics and behavior: in connecting residences and workplaces by trips it used a gravity model of dispersed behavior, but in assigning trips to the highway system it used the deterministic idea of taking only shortest routes. As a paradigm for transport analysis, it has been and is being reworked; in principle its methods can be traced even in divergent but related urban models.

Residential Models: Two Directions and Their Linkages

The major steps in land-use modeling are easily summarized. A series of theoretical models, initially of residential location, were generated by Wingo (1961), Alonso (1964), and Mills (1972) – with other contributions. These models all assumed a monocentric city (having a single employment center), which produced rings of settlement, each occupied by a single residential income class. Density declined and income rose with distance from the center. Residents were trading off commuting costs against space, under the constraints of their income. Mills's model dealt with zones in a linear programming framework, while the other models used continuous space.

The rigor and simplicity of these models inspired efforts to make them operational, hindered by their restrictive assumptions. Herbert and Stevens (1960) developed very early the idea of bid-rents (i.e., specifications of willingness to pay for various types of housing in various locations), and postulated a multicentered city with competition for land in a linear programming format. They did not operationalize the measures of preferences that would underlie a bidding process, or the connection between place of residence and place of work. The National Bureau of Economic Research (NBER) (Ingram et al., 1972) extended this work in a larger operational form, with actual employment centers, a diversity of choice of spatially distributed housing submarkets, and a final determination of residency by linear programming based on the cost of work-to-home travel. Building, remodeling, and redeveloping housing was in a separate supply model.

The alternative route of replicating consumer choice in housing and shopping through the use of a gravity model (that specified a declining probability of choice with increasing distance) was more realistic and more appealing to planning practitioners, but was initiated at the cost of disregarding some economic realities. The Lowry Model (Lowry, 1964) thus gave the appearance of modeling the behavior of all locators (including residents and their choices), and gave room for diversity through a gravity model. The same approach was widely adopted; for a review, see Goldner (1971). It was popularized by Putman (1982) in the USA, and in structure planning and by Echenique in the UK (reviewed in Echenique and Owers, 1994). Most of these efforts went beyond modeling residential choice to consider other locational trends, and other improvements were introduced to make the Lowry Model still more realistic. This model was thus a major contribution to the paradigm shift, by its introduction of a partially unified system of activity location.

The stage was set for a new type of advance that tended to bring these two trends much closer together. The necessity for multicentered models in applied analysis was firmly established. The NBER had introduced a certain amount of diversity through a probabilistic choice of housing markets. Echenique had realized the necessity for constraints on residential location, and began to introduce rents as an incentive for supply and a brake on choice in the face of income limitations. Three important events in the 1970s solidified these advances. In Geography, Wilson (1970) explained the gravity model by analogy with entropy (or constrained randomness) in physics. In Economics, McFadden (1973) formalized the idea of

'discrete choice,' which made diverse behavior acceptable to economists; the gravity model became a special case of this accepted theory. Independently, Anas (1975) showed in a seminal paper that interaction under a gravity model could be constrained by ability to pay in a competitive housing market, leading to an economic equilibrium solution, with market clearing.

All three models – gravity, discrete choice, and maximum entropy – can produce mathematically identical results. There is a common recognition that there are aspects of behavior which are not represented in models, and which contribute to a kind of statistical error in any deterministic explanation. The degree of error varies, and may or may not be susceptible to resolution by further analysis.

Complete Models

While residential choice models are the most important and perhaps the most interesting, a complete model as described at the outset would be a model suite containing numerous submodels. First, land development and its uses are determined by way of locational decisions that in turn are strongly influenced by transport considerations. Putman and Echenique have taken the lead over the last three decades in driving this lesson home – at least to the transport planning community. We will assume that any complete land-use model will embody or interface with an appropriate transportation model and use a forecast of transportation system changes. Second, even the most advanced residential models suffer from some of the general difficulties discussed below, and in particular, models of residential housing supply are weaker than those of demand. Third, models are needed for all land uses, most particularly manufacturing industry and trade and services. With the increasing shift in the overall economy toward business and consumer services, these sectors and their representation in models need thorough review.

There is a modest number of complete model suites publicly available worldwide (see Wegener, 1994, for a review). Putman's ITLUP and EMPAL models have been extended to METROPOLIS, which is widely used, and maintains the Lowry tradition of non-economic constraints. Its employment location is somewhat descriptive in style. Echenique has developed an elaborate input–output framework to generate goods traffic as well as personal trips, with extensive economic constraints. Anas (1987) is continuing to develop a range of economically rigorous and ambitious models, most recently for the New York Metropolitan Transportation Commission (in progress). New work is being undertaken which we cannot elaborate here, but special mention must be made of de la Barra, who follows Echenique in the Americas, and Waddell (2000), who is approaching the residential location from a microeconomic viewpoint in direct collaboration with state planning and transportation studies. Most model sets are provided on a made-to-order basis, which raises their cost and severely limits their availability.

In our judgment, the characteristic nonresidential models have various weaknesses in almost all model sets. The manufacturing sector is undergoing changes that are not yet fully understood and which may upset conventional wisdom. Business services have barely begun to be studied in the locational literature, let alone embodied in models. Retail trade is the best understood of these three fields, but inadequate use is being made of existing knowledge.

Comments on the State of the Art

It is apparent that considerable advances have been made in urban models, but that results are still short of what might be desired. There are still no established scholarly standards in the field, nor is there a clear link between research and practice. Limited tests of models on the same or similar data sets show little unanimity in their conclusions.

There are many social and equity issues being newly faced in planning of all sorts. Some of these have appeared in the USA in the implementation of the clean air act and its amendments, and related issues in transport planning have been litigated. It appears that there is inadequate disaggregation in most models, so that the behavior of minority groups and their reactions to policy inputs could be studied, while some aspects of disaggregation affect the evaluation of transport and planning policy. These needs conflict with the needs for simplicity, transparency, and speedy computation which arise in public discourse.

With increased computer capabilities, microsimulation is appearing as a possible approach to the disaggregation problem, but its relation to the speed of computation must be studied. Indications in the transportation planning field are that it will extend greatly the time required for analysis – and even today transportation models are the biggest bottleneck in operational land-use models.

The growth of urban modeling is linked closely with the expansion of computational power through both mainframe and personal computers. The first steps in modeling were conceptual, and computationally limited in their demands. Growing computer power has made it possible to develop and implement more accurate and more elaborate models. Computing for planning has been decentralized to the desks of planners and administrators. Computer users have readier access to large data sets, now organized in Geographic Information Systems. Research workers of all types have greatly increased power to investigate localized and sectoral phenomena, having better access to computation, data, and modeling methods. All of these investigations contribute to a web of knowledge that expands understanding of urban phenomena, and undergirds improved modeling. Examples include the work of Anas and Waddell discussed above, as well as of specialists like Landis, Cevero et al. (1999), and Shen (2000).

Abstract

This article discusses the emergence of urban history as a subdiscipline in Western Europe and North America from its eighteenth-century origins and considers some of the methodological and theoretical approaches that have informed urban historical studies, ranging from the medieval to the contemporary periods. It considers the emergence of new paradigms of urban history in the rapidly urbanizing societies of South and East Asia and the implications for traditional urban historical scholarship. Finally, it provides an overview of the institutional and associational presence of urban history as a discipline.

Introduction

Urban histories have been written of towns and cities since antiquity: a sense of the past is a crucial component in the construction of a sense of place and local histories documenting a town's antiquity and its achievements continue to inform the wider historical study of urban places. The study of urban history, however, that is the study of towns as particular types of settlement or society, as agents of change, or as the locus of particular social, cultural, or political formations, is of more recent origin, and the emergence of a specific subgenre of academic study is unequivocally a twentieth-century phenomenon. In the twenty-first century, urban history has a clear status as a field of knowledge, although the extent to which it truly forms a distinct academic discipline, with its own methodologies or theories of knowledge, is more debatable. In the words of one urban historian, it is rather a 'focus for a variety of forms of knowledge' about the historical development of towns and cities (Dyos, 1982).

Origins

In the eighteenth century, historians and political economists, such as William Robertson and Adam Smith, recognized the importance of towns as historical agents in bringing about the rise of the modern European state and the system of global commerce that underpinned it, the collapse of feudalism, and the emergence of more widespread participatory politics (Robertson, 1769; Smith, 1776). Other historians drew attention to the role of towns in undermining feudalism by securing liberties and charters from monarchs who looked for commercial benefits and a counterweight against the influence of overmighty barons. They pointed also to the critical role urban society had played in facilitating the exchange of ideas, fostering creativity in the arts and encouraging the growth of civility. Thus, although the emergence of urban history as a field of research was still some distance away, the transformative role played by urban society in the broader narrative of historical development had been clearly identified. Political developments in the nineteenth century directed new attention to the historical urban experience: in Britain, the combination of political and municipal reform in the 1830s focused interest on the historical evolution of urban governance giving rise to some of the first synthetic studies of urban history, as opposed to the purely local study of a single town (Merewether and Stephens, 1835). The rise of democratic movements in Italy and France directed attention backward toward the communes of the medieval period, as historians sought models of more egalitarian and participatory politics in the annals of the medieval city republics (Sismondi, 1809–18). Building on the eighteenth-century recognition of the role of urban society in what would now be called the civilizing process, cities were also recognized as centers of cultural exchange and the arts, even as contemporaries denigrated the cultural philistinism of modern industrial and commercial urban centers. Thus, the Italian renaissance has always been discussed as an urban phenomenon seen through the histories of individual city states such as Florence or Siena (Burckhardt, 1860). But it was the unprecedented growth of the modern industrial city, the achievements of engineering and technology that lay behind it, and the extremes of wealth and poverty that it generated, which directed attention toward towns as the incarnation of modern capitalist modes of production and the nurseries of the modern age.

It was these changes that provoked the German sociologist, Max Weber, to write one of the most influential analyses of urban history of the twentieth century. In *The City* (published posthumously in 1921 and first translated into English in 1958), Weber set out a typological model for understanding the city and its historical development from the consumer/producer cities of antiquity, to the largely autonomous city states of the medieval period, to the age of 'great cities' in the modern era. According to Weber, the western city emerged in the medieval period, defined by its market functions as a center of exchange, but also by its administrative autonomy in feudal society, its system of corporate governance and modes of association that were independent of ties of kinship or personal fealty, and its status as a defensive organization given physical form in the city walls. Weber's conception of the city was an 'ideal type' and one that was shaped by his own understanding of the rise of democracy and participatory politics as the natural end of civil society. He excluded from his definition of the city both the settlements of Eastern Europe which were subject to feudal overlords and

'oriental' cities, such as Edo or Peking, despite their size, because they failed to display the requisite degree of autonomy and corporate governance. The model can be recognized today as Euro-centric, gender blind, and of limited use in an age of global cities and urban conglomerations or urban regions, but nonetheless it continues to carry value as a heuristic tool and remains an important reference point in historical discussions of urbanity.

At the same time, the rapid pace of urban growth and industrialization in Western Europe and the USA focused the attention of reformers, economists, and philanthropists upon the city as a source of social problems and unexpected failures, as well as the engines of prodigious wealth generation and expansion. The city became an object of study and an entity to be described, planned, and controlled. This line of enquiry is perhaps more accurately seen as laying the foundations for urban sociology where attention was focused upon finding explanations and solutions to the problems of modern urban society. This was a field of research in which the Chicago School of Sociology led the way in the 1920s and 1930s. Of particular significance to the development of urban historical studies would be the work of Robert Park and Ernest Burgess, who applied a theory of human ecology to urban development, arguing that competition for land and resources inevitably led to differentiated zones of deprivation and affluence (the concentric zones theory) and Louis Wirth who concentrated on the way in which human behavior adapts to both the urban environment and the social structure of cities, a theme most famously articulated in his essay 'Urbanism as a way of life' (Park et al., 1925; Wirth, 1938).

Emergence of a Subdiscipline

Building on these developments, historians on both sides of the Atlantic in the postwar era made a deliberate attempt to move away from the 'urban biography,' the study of a particular town. Rather, they set about identifying urban systems and typologies based on scale (capital cities, metropolitan cities, megalopolis, administrative units), function (ports, railway centers, textiles, shipbuilding and heavy engineering, iron and steel, spas, tourist centers), categories (industrial cities, new towns, Mediterranean cities, imperial cities, sun belt/rust belt cities), or ideology (capitalism, communism, utopian planning): analytical tools which continue to be a staple of urban historical analysis. They also focused upon common processes: the development of capitalism, urbanization, and the emergence of a distinctive urban consumer economy or the interaction between property, power, and social relations, using thematic studies based on transport, demography, property ownership, income, and occupational patterns. From this perspective, an understanding of the particular evolution of an urban settlement might be significant in the local context, but for urban historians it was more important to locate such information within a broader understanding of systems of power or social relationships. The urban historian, in other words, sought to generalize and rise above the unique particularities of local studies that so often sustained the civic pride of antiquarians and local historians. This pursuit of the general rule, the sense of what was typical, was very much in tune with the positivism of social science–based research in the 1950s and 1960s, particularly in the Anglo-phone world. This was the period when economic history was riding high and the advent of new technologies, such as main frame computing opened up new possibilities for the quantitative analysis of evidence and the creation of statistical data from which generalities could be drawn and probabilities asserted. Social science-based historical research exercised a profound influence on urban history, where the town represented the locus within which economic and social change could be studied, but also constituted a peculiar nexus of social, economic, and cultural factors, often described as the 'urban variable.'

Within this urban history agenda, medievalists and early modernists were often uncomfortable with theory and a form of quantitative empiricism which often depended upon evidence of a kind which simply did not survive from earlier periods and, crucially, an assumption that urban history is essentially the story of urbanization, and the parallel narratives of industrialization, democratization, and modernization. Their concerns were various: the medieval and early modern town was a very different phenomenon to that of the nineteenth or twentieth century. There was even considerable debate as to what constituted urban status in a period when few towns in Europe exceeded 10 000 people and many were far smaller: a size that no modern historian would recognize as urban. All towns must be understood in relation to their hinterlands, but in an essentially agrarian economy, medieval and early modern towns need to be studied as part of much broader systems and processes in which a distinctive urban experience is less easily isolated and defined than in the modern period. Quantification, which was axiomatic for so many of the questions posed by historians of the modern city, was often problematic: even establishing basic population figures for medieval and early modern urban settlements has been a challenge. The value systems of medievalists and early modernists also sat uncomfortably with those analyzed by urban historians of the modern period. Questions of legal status, systems of authority, or the organizing role of religion have loomed large. Concepts of class or systems of governance, by contrast, were far less important. Rather than urban growth, it was frequently decline and decay that attracted historians' attention. At times, it seemed that there was little in common between the towns of medieval Europe, which numbered a few thousand or less, and the great cities of the nineteenth and twentieth centuries of Europe and North America. This temporal divide hardened, with social scientists dominating urban historical writing in the period after 1750 and historians colonizing the earlier period – crudely a division either side of the main thrust of industrialization and modernization in Britain. This in itself is a (social science based) generalization, but the emergence of a separate Pre-Modern Towns group in 1987 in the UK was an expression of this intellectual and philosophical divide in Britain, and the disciplinary distinction between social scientists and historians in their respective approaches to towns and cities should be acknowledged.

More recent developments in historical writing have encouraged something of a rapprochement between historians across this chronological divide in the UK and Western Europe, at least. (In the USA, the study of colonial urban history, while vigorous, continues to be heavily overshadowed by studies of

the modern American city; beyond Europe and North America, a different temporal framework applies, see later text.) Since the 1980s, the rise of cultural history, the linguistic turn, post-modernism, and the influence of the later Annales School (as reflected in interest in the construction of historical mentalités, for example) cast doubt on the empiricism and the theoretical assumptions of the social science–based approaches. Quantitative methods, which were implicit in much early social science–based urban history, could be criticized for having reified towns as depersonalized, abstract entities which simply grow or decline, which experience problems or resolve them. Such an approach distorted the nature of historical inquiry by focusing on issues and questions for which quantifiable sources exist, and by marginalizing aspects of urban life which did not lend themselves so easily to quantification, such as women's work or the experience of the marginal poor. Urban history, as Griffiths and Jenner observed, was rendered as 'a series of graphs and tables, or a succession of maps' (Griffiths and Jenner, 2000). More recently, however, the opportunities offered by personal computing and the digitization of historical sources have altered the balance of historical enquiry yet again. The quantitative and qualitative can be combined ever more effectively and with greater sophistication due to the rapid steps taken in digital software and the emergence of a new field of digital humanities: the potential is evident in projects such as 'London Lives' which allow the researcher to combine the qualitative, microhistorical approach of researching the personal history of an individual with the ability to retrieve data on a macroscale through 15 different datasets created from 8 archives and comprising over 3.35 million names.

Interdisciplinarity

Urban history has defied definition, embracing as it does all aspects of the history of urban settlements whether as physical structures, economic entities, or communities of people. Its catholicity has also been reflected in its multi- and interdisciplinary approach to the past. The early gatherings of urban historians in North America and in Europe, respectively, included economic historians, sociologists, geographers, and architectural and planning historians. While geographers and planners are principally concerned with questions concerning the production, use, and meaning of space, historians share these interests but with a greater emphasis on the temporal dimension, extending their analysis across time. Influenced by theoretical works such as Henri Lefebvre's La production de l'espace (1974; translated into English, 1991) historians, and urban historians in particular, have sought to 'spatialize' understandings of identity, social relations, and human activity. The urban environment and the material fabric of streets, houses, and public buildings can no longer be seen as passive actors in the historical process: rather urban space both molded and was molded by the behavior and actions of urban inhabitants. The advent of more sophisticated mapping technologies through the development of GIS has allowed urban historians to open up new agendas in both the analysis of the spatial dimensions of urban society over time and also the presentation of research results. The potential to visualize data through mapping techniques is evident in projects such as the hypercities project at UCLA and Visualizing Urban Geographies, a collaboration between the National Library of Scotland and the University of Edinburgh.

Other historiographical developments, such as the 'linguistic turn,' and the school of cultural history which grew from it, directed urban historians toward the analysis of language and the way in which it shaped perceptions of identity and experience, particularly in terms of social status, class, and gender. This has been an approach that has lent itself to sources from antiquity to the twentieth century. The concentration of people within towns and cities and the rich potential for different forms of communication in urban society multiplied the opportunities to establish and create meaning or express identity. The emphasis on 'experience and identity' as a category of analysis has also opened up new avenues for urban historians to explore which were previously ignored or regarded as incidental, for example, the sensory dimensions and experience of the city – its sight, smell, touch, and sound – and the emotions that the city provokes.

Historians of medieval and ancient cities have always cooperated closely with archaeologists being heavily dependent upon the evidence of material remains for understanding of both the physical structure and social life of the town. Maurice Beresford notably drew upon archaeological evidence for his path-breaking study of medieval planned towns (Beresford, 1967): a key text that refuted earlier assumptions that urban planning was an attribute only of modernity. This kind of collaboration characterizes urban history wherever excavations have taken place, whether the British Iron Age town of Silchester (where archaeological evidence has transformed our understanding of British urban settlements prior to the Roman conquest (Fulford, 2012)) or the Japanese medieval castle town of Ichijo-dani, constructed in 1472 and destroyed in 1573. Historians and archaeologists studying classical and medieval urban settlements, influenced by cultural and spatial theory like their counterparts in later periods, have recently attempted to move beyond the description of topographical and architectural developments as ends in themselves, recognizing that the physical structure of towns was an embedded part of daily life, political institutions, and religious belief. Equally, archaeologists have become more interested in the activities within the physical structures as well as nonarchitectural or 'activity spaces' and the history of the everyday bringing the agenda of urban historians and archaeologists ever closer (Grig, 2013).

The convergence also reflects the 'material turn' in historical studies: in recent years, historians have been moving away from a text-centered approach to the past and have become increasingly appreciative of the insights to be derived from studies of material culture for later periods, as well as those for which little in the form of textual evidence remains. This greater openness to using material culture has also influenced urban history on a conceptual level by decentering the importance of human agency (drawing also on Actor Network Theory) and focusing attention on the agency of inanimate objects, buildings, spaces in shaping the behavior of individuals and society at large. Histories of the automobile and of roads, for example, demonstrate how these inanimate objects and structures have a powerful determinative impact on human agency in the

urban context, while historians of the nineteenth-century city have analyzed how the modern liberal society was brought into being through techniques of governance that depended on an infrastructure of water, sewerage, gas, and electricity (Gunn, 2011; Joyce, 2003; Otter, 2008).

As the temperature of the global village rises, a historically informed understanding of the interaction between cities and the environment has become increasingly pressing. In the latter half of the twentieth century, the field of urban environmental history has emerged as historians seek to understand urban society as the product of the relationship between human agency, technology, and nature and to recognize the fundamental and irreversible changes that modern urban society has wrought upon the globe (Chakrabarty, 2009). Although the urban form is often seen as 'unnatural,' that is, man-made in contrast to the 'natural' rural or agrarian landscape, environmental historians break down that distinction, demonstrating how towns and cities have exercised a profound influence over the surrounding countryside, reshaping 'nature': an approach that is exemplified in William Cronon's study of Chicago (Cronon, 1991). Another highly topical area of urban environmental research lies in the histories of pollution (water, air, noise) which almost always have an urban focus, as towns are the primary sources of pollutant activity. This approach to urban environmental history is often concerned with questions of social justice and inequality, and the interplay of race, gender, and class in urban environmental politics.

As the comments above might suggest, urban history always stands in danger of losing its coherence as a particular approach, due to its inherent interdisciplinarity. At the other extreme, there is also a tendency to assume that anything, by virtue of taking place in a town or city, can be said to qualify as urban history. For most urban historians, however, the urban context is a necessary though not a sufficient condition, because the urban dimension itself may be considered an independent actor in the process of change and development in towns and cities. As the British historian H.J. Dyos explained:

> the authentic measure of urban history is the degree to which it is concerned directly and generically with cities themselves and not with the historical events and tendencies that have been purely incidental to them … it is the study of the characteristically symbiotic relationships of their (cities') different characteristics, of the ways in which their components fitted together or impinged on other things that distinguishes urban historians from those who may be said merely to be passing through their territory. (Dyos, 1974)

Questions of identity and social experience, meaning and representation, environment and material culture equally transcend the chronological and the disciplinary boundaries. If the distinctiveness of urban history as a discipline is no longer so clearly demarcated in the twenty-first century, this is due to changes in the nature of historical discipline itself rather than to any crisis of confidence in the validity of the town or city as the object of historical research. The 'cultural' turn, for example, as noted above, has helped to dissolve the boundaries between many different subgenres of history, not just urban history. The cogency of urban history as a framework for historical inquiry, however, remains powerful and it continues to evolve in new directions.

Globalization

Urban history as a field of study emerged in Western Europe and North America largely in response to the specific historical circumstances of rapid urbanization, industrialization, and, in Western Europe, postwar reconstruction, which focused historians' and sociologists' attention upon urban society as a field of paramount importance for academic research. In the postcolonial era, there has been a global shift in attention as South America, Asia, and to a lesser extent Africa have undergone their own process of rapid urbanization. Just as in Europe and North America, much urban history in Asia, Africa, and South America was originally constituted of local studies and urban biographies, but increasingly urban historical scholarship in these areas has taken a more conceptual and comparative approach. The experience of urbanization in China and India, for example, challenges many of the paradigms by which Western urban history has been understood: the scale of the problems (and opportunities) faced by Asian cities dwarfs those of the Western experience of urbanization, and there is a telescoping of changes and processes for which there is equally no Western parallel: demographic expansion, industrialization, the emergence of democracy, the communications revolution – all of which in Western history followed sequentially – are taking place simultaneously and introducing an entirely new paradigm of urbanism. The models by which we have traditionally understood modernization and urbanization are being systematically upstaged.

Developments in the history of Chinese cities reflect those in the wider urban historiography. In the mid-twentieth century, a Eurocentric view of urban history saw Imperial China as static and autocratic, only spurred into modernization by the arrival of the West in the nineteenth century. It was argued that the form of Chinese cities reflected a long-established Confucian cosmology and that culturally they were indistinct from the countryside (Mote, 1971). Latterly, historians began to consider how internal events were equally, if not more, important than external influences in bringing change to China. This led to a reassessment of the history of cities, and two trends have dominated scholarship. The first views cities in Imperial China as dynamic, with complex commercial, cultural, social, and political identities, while the second explains the emergence of urban modernity as a result of both indigenous and external factors. Thus, for example, the former capital Kaifeng had a population of at least 1 million, and was characterized by lively markets, painting, poetry, and guidebooks, as well as sites of worship. Later, despite the disruption of dynastic overthrow, cities retained and developed their own distinct identities. Merchants of all classes formed large-scale trading networks that reached across the empire and abroad, while proto-industries in cotton, silk, and other sectors developed.

By the collapse of the Qing dynasty in 1911, treaty ports, the outposts of colonialism in China, had already been transformed by modern innovations such as new roads, sewage systems, department stores, and a vibrant print culture.

While it is true that Shanghai emerged as the center of Chinese urban modernity, historians now recognize that other cities were not simply copies of this metropolis. Histories of cities as far afield as Chengdu in Western China and Harbin in the north reveal how economic and political elites relied on local elements as much as global notions of urban modernity to create hybrid identities. Despite the disruption of the Anti-Japanese War of Resistance and the Communist revolution of 1949, we are now beginning to understand that even as urbanization stretches across whole regions, such distinctive identities continue to shape the development of cities in the twenty-first century.

In India and South Asia, the village and not the city has traditionally dominated both national self-perception and the outsider's view of the country. Weber dismissed Indian towns because they lacked the defining sense of unitary community that he identified in the West; rather they were simply loose federations of extended families, castes, or occupational groups (Gupta, 1981). For Indian nationalists, the city was associated with colonial rule and was regarded as a Western import, while the movement for independence was rooted in rural society, where Gandhi located the true India. Under imperial rule, it was assumed, a handful of presidency cities such as Madras, Bombay, Delhi, and Calcutta, and a clutch of railway towns had burgeoned; the others suffered deindustrialization and deurbanization throughout the nineteenth century. Postcolonial and subaltern studies reinforced this antiurban tendency, with a literature where rural society and peasant farmers, rather than the urban proletariat, were foremost. Serious interest in the city did not begin until the 1950s when sociologists and economists began to study the processes of urbanization in response to the influx of post-partition migrants to Indian cities after 1947. The field was dominated by sociologists and anthropologists, however, and a historical dimension was missing until the 1960s when historians began to recognize the importance of the city as a backdrop – if not as an agent or a 'variable' – in the emergence of modern politics and nationalism and in the processes of industrialization and modernization. By the 1970s, Indian historians, influenced by some of the same historiographical trends as in the West, began to focus more upon the city as the theater for the display of colonial power through architecture and the built environment, on the social history of the urban working classes, and on the public culture of colonial Indian cities. The foundation of the Urban History Association of India in 1978 bears witness to the emergent profile of the field. But it is the astonishingly rapid urbanization of the last 30 years – Indian cities now account for more than 10% of the world's urban population – that has directed attention toward the city and its colonial as well as the postcolonial past. Economic liberalization and globalization have created a newly wealthy and influential urban middle class: the same forces have also reshaped Indian cities and deepened the inequities of wealth and political opportunity and as such the city is the object of renewed historical study, shaped by both its colonial and postcolonial past. Even more so than in China, the urban history of India has had to engage with the historiography of the West, but what the more recent literature has demonstrated is the hybridity of Indian urbanism: colonial models of urban governance were imported, but they were also modified, resisted, and adapted in the colonial context, giving rise to a very different version of indigenous modernity and urbanism.

As South Asia, China, and parts of Africa undergo unprecedented urbanization and represent an ever-increasing proportion of the world's urban population, the study of urban history is losing its Eurocentric focus and taking on an increasingly global perspective: urbanity and modernity are being reconfigured and traditionally held assumptions regarding periodization and the origins of urban modernity in the West or the dominance of Western forms of urbanism have had to be refined. Questions of urban historical process such as the relationship between state power and urban governance or the growth of civil society and the rise of the public sphere have to be seen now in global perspective (Kidambi, 2007). The emergence of 'world cities' such as Bombay and Delhi, Shanghai, and Singapore, as well as London and Los Angeles as the crucial nodal points of global networks makes them key players in the emergent field of transnational history which looks at interactions and developments beyond the nation state and across continental boundaries. The field of transnational and global urban history is one which is rapidly expanding and opening up a rich seam of new questions and new directions.

Institutionalization

The institutionalization of urban history can be traced through the establishment of dedicated research chairs, research centers, formal associations of scholars, publications, and the presence of urban history within university curricula. The formal institutionalization of urban history goes back to the early twentieth century when the Stockholm Institute for Urban History was founded by the confederation of Swedish Towns in 1919, a development which led later to the establishment of the world's first chair in urban history at the University of Stockholm in 1953. The inspiration for the Swedish Center for Urban History, however, was rooted in the traditions of urban biography and localism (its remit was the ordering and publication of documents relating to the history of Swedish towns). A different version of urban history began to be formalized, however, at around the same time: across the Atlantic in 1953, a loose association of American academics agreed to meet informally to discuss urban history, deliberately distancing themselves from both the traditions of antiquarianism in the European tradition and the urban boosterism that was characteristic of North American cities. A regular series of conferences and publications followed in a movement that was identified as the 'new urban history' (Stave, 1977). Nine years after the North American Urban History group held its first meeting, H.J. Dyos of the University of Leicester and other colleagues belonging to the Economic History Society formally met as the Urban History Group 1962 in the United Kingdom. During the late 1950s, 1960s, and 1970s, associations of urban historians were established across Europe and further afield, such as the Arbeitskreis für landschaftliche deutsche Städteforschung (1959) and the Arbeitskreis für südwestdeutsche Stadtgeschichtsforschung (1960) and the Dutch Urban History Group in 1974. Beyond Europe, the Tokyo Study Group in Comparative Urban

History was formed with six charter members in 1971, for example, and the Urban History Association of India, as noted above, was established in 1978.

While most of these national associations were also interested in urban history beyond the national boundaries, there was also a strong international and collaborative impulse to urban historical research as countries across Europe had to come to terms with the devastation that World War II had wrought upon towns and cities and sought to put the conflict of the first half of the twentieth century behind them. In this spirit, the International Commission for the History of Towns (ICHT) was established in 1955: 'pour objet d'établir des contacts et de faciliter la coordination des recherches entre les spécialistes de toutes les branches de l'histoire des villes' (to establish contacts and to promote the coordination of research between specialists in all areas of the history of towns and cities). In a similar vein, the Institute für vergleichende Städtegeschichte was established in Munster in 1969. The most notable achievement of the ICHT to date is the support given to the Historic Towns Atlas project, the aim of which is to coordinate the production of atlases of towns plans, to common scales, accompanied by commentaries and subsidiary maps, to facilitate the comparative study of the history of European towns.

Comparative European, and increasingly comparative global urban historical research, is also fostered through the biennial conferences of the European Association of Urban Historians (EAUH), established in 1989. The lists of sessions of recent conferences give a fair indication of current trends in urban history with themes such as environment, heritage, deindustrialization, consumption, and construction of community all areas of particularly topical concern, obviously reflecting contemporary priorities in wider society. Recent conferences have also seen a marked increase in scholars from the former Eastern Bloc, who were formerly isolated from the traditions of Western European and American historical writing, for whom topics such as the legacy of industrialization and deindustrialization for modern cities and the problems of urban sustainability are particularly pertinent. These conferences also serve to showcase methodological advances, and in particular the progress that has been made with IT-assisted mapping and GIS as well as the construction of other digital resources. In the USA, the Urban History Association and Society for American City and Regional Planning History hold conferences in alternate years, and while their focus is chiefly upon the urban and planning history of North and South America, their meetings are similarly taking on an increasing global and transnational perspective.

Once scholars had identified a common interest in urban history and formed an association, publications soon followed, initially in the form of newsletters to disseminate information, but invariably leading to the emergence of journals dedicated to urban historical research. Thus the *Journal of Urban History* which first appeared in 1974 has its origins in the Urban History newsletter of the 1950s and 1960s. In the United Kingdom, H.J. Dyos was similarly inspired to issue his British newsletter until 1974 when its publication was formalized as the *Urban History Yearbook*. This, in turn, evolved into the *Urban History Journal* published by Cambridge University Press in 1991. While *Urban History* and *Journal of Urban History* share a comparative approach and global coverage, many other urban historical journals have emerged in the last 50 years with a stronger national or regional approach, including the German journal *Städteforschung* (first issued in 1970), *Stadsgeschiedenis* (covering Belgium and The Netherlands), *Città e Storia* (primarily Italy), and *Histoire Urbaine* (predominantly France) while in Japan, *The Comparative Urban History Review* focusing on Japanese urban history has been published twice a year since 1982.

The establishment of research centers dedicated to urban history at various universities has helped to ensure that the subject maintains an institutional profile and a presence in the curricula of undergraduate and postgraduate courses (Rodger and Menjot, 2006). H.J. Dyos became the first professor of Urban History in the United Kingdom; following his death in 1978, the tradition of urban history at Leicester continued, with the foundation of the Center for Urban History in 1985. Its current priorities reflect some of the key developments in urban history of recent years: an emphasis on the importance of transnational approaches and recognition of the importance of Asia (notably China and India) in modern urban history and the nature of urban heritage and the management of the past for cities in postindustrial society. Other specialist research centers for the study of urban history include the Center for Metropolitan History at the Institute of Historical Research, University of London, the Center for Urban History, University of Antwerp, the Danish Center of Urban History at the University of Aarhus, and the Center for Urban History of East Central Europe at Lviv.

Urban Informality: The Production and Regulation of Space

Ananya Roy, University of California, Berkeley, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Urban informality is a polyvalent concept with roots in the debates of the 1970s about capitalism, informal work, and marginality. Most recently, urban informality has come to signify either an apocalyptic vision of a global epidemic of slums or a utopian vision of entrepreneurial poverty and improvised urbanism. Eschewing such conceptualizations, in this article, I present urban informality as a mode of the production and regulation of space. Urban informality is thus a heuristic device for understanding the territorial practices of state power and the processes of capital accumulation.

Urban informality has recently emerged as a prevalent concept in urban theory and research. However, the term is increasingly deployed in multiple and often divergent ways, rendering the concept somewhat chaotic. In addition, the distinctive genealogy of the term is often overlooked, thereby obscuring the historically specific political economy that the concept is meant to illuminate. In this article, I seek to explain the concept of urban informality in the following ways. First, I trace its genealogy to the debates of the 1970s about the structural logic of capitalism. Second, I show how today the idea of urban informality has been revived in the crucible of debates about urban citizenship. Third, I put forward the provocation that to truly consider the 'urban' character of informality requires us to think about the production and regulation of space. In particular, I argue that urban informality is best understood as a heuristic device that makes possible an analysis of the territorial practices of state power. Finally, I conclude by sketching emergent debates about informality, especially those that return us to the relationship between informality and the future of capitalism.

The Informal Sector

The term *informal* can be traced to the work of Keith Hart and the International Labor Organization (ILO) in the early 1970s. While modernization theory struggled to explain how a 'marginal mass' was not absorbed by industrialization, Hart showed that such forms of marginality and informality were a structural feature of urban economies. Writing in the context of Accra, Hart (1973: 61, 68) identified a "world of economic activities outside the organised labor force" carried out by an "urban sub-proletariat." Hart designated these activities as informal. At more or less the same time, the ILO (1972) in Kanbur, (2009) defined the informal sector as the activities of "petty traders, street hawkers, shoeshine boys and other groups 'underemployed' on the streets of big towns, and includes a range of wage-earners and self-employed persons, male as well as female." Hart's conceptualization of informality has been commonly interpreted as "the relationship of economic activity to intervention or regulation by the state" (Kanbur, 2009: 5). This is accurate. In a recent reflection on his 1973 paper, Hart (2006: 25, in Kanbur, 2009: 2–3) notes that, following Weber, he had argued "that the ability to stabilise economic activity within a bureaucratic form made returns more calculable and regular for the workers as well as their bosses. That stability was in turn guaranteed by the state's laws, which only extended so far into the depths of Ghana's economy." Informal work lay outside this realm of calculable and stable transactions and was thus erratic, with low returns.

In many ways, Hart's argument is a companion to the conceptualization proposed by dependency theorists: that the state maintains the informal economy in unregulated form in order to subsidize a system of global capital accumulation (Portes et al., 1989). Indeed, a whole generation of social science research, much of it produced in Latin America, was to explode the 'myth of marginality' (Perlman, 1977) and show how informal work and habitat was an integral part of the capitalist city, especially the 'dependent city' at the periphery of the world-system (Castells, 1983). But Hart went further. Unlike later interpretations of the informal sector, he "did not identify the informal economy with a place or a class or even whole persons" (Hart, 2006: 25). Instead, he argued that many of Accra's residents sought to forge a multiplicity of livelihoods and income opportunities, in other words that informality was a generalized condition, a way of life if you will. I will return to this idea of informality as a way of life later in this article.

Hart's conceptualization of the informal sector closely resonates with more contemporary interpretations of informality, especially scholarship that traces the formation of a "new urban marginality"–not only in the Global South but also in Europe and the Americas. Wacquant's work (1996, 1999, 2007), for example, documents the emergence of an "advanced marginality" that is linked to the "territorial stigmatization" faced by residents of marginalized spaces: the ghetto, the banlieue, the favela. Similarly, Auyero (2000) charts the emergence of the hyper-shantytown. Such research is united in its emphasis on the connections between such advanced marginality and the hollowing out of economies and welfare states through neoliberal capitalism. The hyper-shantytown is thus produced by 'hyper-unemployment' (Auyero, 1999), a systematic process of deproletarianization and labor informalization. While the theorists of advanced marginality acknowledge the poverty-targeting efforts of the state (for example, in Brazil, the upgrading of favelas through the provision of services), they insist that such programs are minor palliatives in the face of a massive structural crisis. In particular, they argue that the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74051-7

communities of the urban poor are now overwhelmed by violence: the violence of state repression, the symbolic violence of stigma and discrimination, and the material violence of poverty and unemployment (Perlman, 2003). In short, yesterday's 'slums of hope' are today's 'slums of despair' (Eckstein, 1990: 165).

Perhaps the most prominent interpretation of informality as the structural logic of capitalism is Mike Davis's (2004) apocalyptic account of a planet of slums. For Davis (2004: 14–15), informal urbanization is a stark manifestation of 'overurbanization' or "urbanization without growth," which in turn is "the legacy of a global political conjuncture – the worldwide debt crisis of the late 1970s and the subsequent IMF-led restructuring of Third World economies in the 1980s." Davis (2004: 23) thus designates this world-system as a "planet of slums," a warehousing of the "surplus humanity" released by deproletarianization and agricultural deregulation in hazardous and miserable forms of urban settlement. He concludes that "informal survivalism" is "the new primary mode of livelihood in a majority of Third World cities" (Davis, 2004: 24).

Urban Citizenship

Mike Davis's account of a planet of slums is accompanied by considerable anxiety about the urban politics of informality. Davis (2004: 28) asks: "To what extent does an informal proletariat possess that most potent of Marxist talismans: 'historical agency'?" He concludes that "uprooted rural migrants and informal workers have been largely dispossessed of fungible labour-power, or reduced to domestic service in the houses of the rich" and that thus "they have little access to the culture of collective labor or large-scale class struggle." Davis's lament rehearses a much older argument presented by dependency theorists. For example, in the seminal text, *The City and the Grassroots*, Castells (1983) presents an ambitious theory of urban social movements. Studying both formal political organizations and the mobilizations of informal squatter communities, Castells acknowledges the central role of politics in the transformation of the capitalist city but also analyzes the limits of such politics. In particular, he designates the populist politics of squatter communities as a symptom of the "dependent city," a "city without citizens." He argues that while squatters mobilize to secure access to land, services, jobs, and at times even tenure, they are simultaneously co-opted into systems of political patronage. Thus, they are clients rather than citizens, disciplined subjects of urban populism rather than active agents of structural change.

Such understandings of urban politics are directly contradicted by a new genre of scholarship that positions informality as the material basis of formations of urban citizenship. For example, in his work on South Asia, Chatterjee makes a distinction between a bourgeois civil society and the political society of the urban poor. Civil society is bourgeois society and in the Indian context, an arena of institutions and practices inhabited by a relatively small section of people able to make claims as fully enfranchised citizens. By contrast, political society is the constellation of claims made by those who are only tenuously and ambiguously right-bearing citizens. The "paralegal" practices and negotiations of political society is for Chatterjee the politics of much of the people in most of the world: "The paralegal then, despite its ambiguous and supplementary status in relation to the legal, is not some pathological condition of retarded modernity, but rather part of the very process of the historical constitution of modernity in most of the world" (Chatterjee, 2004: 75). His work echoes that of Appadurai, who sees in the political actions of Mumbai's slum-dwellers a form of deep democracy, a counter-governmentality that challenges the top-down strictures of planning and development. Similarly (Benjamin, 2008: 721), makes the case for occupancy urbanism, the appropriation of urban space by poor groups. Most recently, Holston (2007: 4) has argued that the auto-constructed peripheries of Brazilian cities are the site of new imaginations and practices of urban citizenship, what he calls insurgent citizenship or where citizenship is produced "not primarily through the struggles of labor but through those of the city."

What is at stake in such work is the conceptualization of informality as an alternative urban order, a different way of organizing space and negotiating citizenship. AlSayyad (2004) thus presents the idea of "urban informality as a way of life." His title refers to the classic 1938 essay by Wirth, "Urbanism as a Way of Life." AlSayyad argues that today urban informality is a generalized urban condition. In a similar vein, Bayat (2007) argues that informality is the "habitus of the dispossessed." In earlier work, Bayat (2000), working in the context of Middle Eastern cities, outlined the repertoire of tactics through which urban 'informals' appropriate and claim space. According to Bayat, this "quiet encroachment of the ordinary" by subaltern groups creates a street politics that shapes the city in fundamental ways. Bayat's analysis is similar to Michel de Certeau's (1984) conceptualization of the "practice of everyday life" as a set of tactics that can undo the oppressive grid of power and discipline. In similar fashion, Simone (2006a, b) presents the African city as pirate towns, where urban residents develop forms of everyday practice that allow them to operate resourcefully in underresourced cities. This is a context of crisis, where "production possibilities" are severely limited; but this is also a context where "existent materials of all kind are to be appropriated" (Simone, 2006a,b: 358). While Simone does not use the term *informality*, his analysis suggests that he is describing practices that can be designated as such:

> African cities are characterized by incessantly flexible, mobile, and provisional intersections of residents that operate without clearly delineated notions of how the city is to be inhabited and used. … These conjunctions become an infrastructure—a platform providing for and reproducing life in the city. (Simone, 2004: 407–408)

Such conceptualizations of urban informality are also shaping the professions of architecture and urban planning. Indeed, informality is the inspiration for the imagining of urban futures. It is thus that star architect Rem Koolhaas interprets the urbanism of Lagos as a 'culture of make-do' (Enwezor, 2003: 116). In his encounter with Lagos, part of Harvard's Project on the City, Koolhaas is taken with the inventiveness of its residents as they survive the travails of the megacity. He sees such experimental responses as generating "ingenious, critical alternative systems," a type of 'self-organization' creating "intense emancipatory zones" (Godlweski, 2010). Koolhaas draws the following conclusion: "Lagos is not catching up with us. Rather, we may

be catching up with Lagos." In similar fashion, in 2011, the Center for Architecture in New York hosted an exhibition titled "Jugaad Urbanism: Resourceful Strategies for Indian Cities." Curated by Kanu Agrawal, the collection of models, photographs, and video installations sought to highlight the 'inspired, duct-taped ingenuity' of communities of poverty. From tin-can canopies to frugal latrines, the exhibition was meant to capture how the poor 'make-do' and how such forms of making-do are a new idiom of urban ingenuity and entrepreneurialism:

> Set in the radically uneven urban landscapes of Delhi, Mumbai, Ahmedabad and Pune, India, Jugaad Urbanism explores how the energy of citizens "making-do" is translated by architects, urban planners, and governmental and nongovernmental entities into efficient and inventive strategies for sustainable urban growth. From energy-generating spinning wheels to the extensive skywalks of Mumbai—the exhibition highlights how 'jugaad' interventions (a term in Hindi used to describe an innovative, resourceful approach) are challenging traditional spatial hierarchies and mechanistic planning principles.
> (http://cfa.aiany.org/index.php?section=upcoming&expid=136)

The Jugaad Urbanism exhibition is an example of a new global imaginary about poverty, which views the economies of the poor as economies of entrepreneurship and dynamic informality. I will discuss the implications of such an approach in the concluding section of this article.

The Production and Regulation of Space

In his initial analysis of the informal sector, Keith Hart put forward a cautionary note that is as valid today as it was in 1973:

> Socialists may argue that foreign capitalist dominance of these economies determines the scope for informal (and formal) development, and condemns the majority of the urban population to deprivation and exploitation. More optimistic liberals may see in informal activities, as described above, the possibility of a dramatic bootstrap operation, lifting the underdeveloped economies through their own indigenous enterprise. Before either view—or a middle course stressing both external constraint and autonomous effort—may be espoused, much more empirical research is required. (Hart, 1973: 88–89)

Taking up Hart's caution against structuralist and populist views of the informal sector, I now turn to a different conceptualization of urban informality. With particular attention to the "urban" character of informality, I suggest that informality must be understood as a mode of producing and regulating space. In particular, urban informality is best understood as a heuristic device that makes possible an analysis of the territorial practices of state power. Such a definition has three implications. First, it means that informality is not a separate and bounded sector of unregulated work, enterprise, and settlement but instead a pervasive socio-spatial logic. Indeed, as (AlSayyad, 2004: 25) has noted, what requires explanation is not so much informality as a way of life as it is formality, as a 'new mode' of urbanism, one that "was introduced to organize urban society only in the nineteenth century." Second, the entanglement of formality and informality suggests that no legal or regulatory boundaries can be drawn between these domains. The formal and the legal are perhaps better understood as fictions, as moments of fixture in otherwise volatile, ambiguous, and uncertain systems of spatial regulation. Indeed, in my work on Calcutta (Roy, 2003), I have shown that informality exists at the very heart of the state and is an integral part of the territorial practices of state power. This builds on the previous work of (Meagher, 1995: 259, 279) who calls for a conceptual shift "from informality represented as a marginalized sector to 'informalization' conceived as a wider economic response to crisis," and notes that such a process of "informalization" does not happen "outside the state" but rather is a "socioeconomic restructuring instigated by the state." Finally, to conceive of informality as a mode of producing and regulating space implies that informality cannot be seen to be synonymous with poverty. The splintering of urbanism does not take place at the fissure between formality and informality but rather, in fractal fashion, within the informalized production of space. A closer look at the metropolitan regions of much of the world indicates that informal urbanization is as much the purview of wealthy urbanites and suburbanites as it is that of squatters and slum-dwellers. The urgent question then becomes how and why elite informalities are valorized and even regularized while subaltern informalities are criminalized.

Such issues have been taken up in considerable detail in recent scholarship on urban informality. Gidwani (2006: 12) describes how unauthorized farmhouses, built illegally on agricultural land, dot the periphery of Delhi. "The owners of these farmhouses, notables on Delhi's social circuit, are often the very same people who profess an urban environmentalism and advocate the 'cleaning up' of Delhi." The "cleaning up" of Delhi has usually entailed the dispossession and the displacement of the poor through slum evictions and demolitions, what Baviskar (2003) provocatively titles, "bourgeois environmentalism." Similarly, in the case of Mumbai, Weinstein (2008: 23) highlights the construction of new shopping centers, many of them built illegally by the city's "largest and most notorious mafia organization, on land belonging to the state government's public works department." Indeed, as she notes, this mafia organization was running "a highly profitable property development business since the mid-1990s, constructing retail and residential buildings in other parts of Mumbai, as well as in Dubai and Karachi." It is thus that Ghertner (2008) notes that almost all of Delhi violates some planning or building law, such that much of the construction in the city can be viewed as "unauthorized." He poses the vital question of why some of these areas are designated as illegal and worthy of demolition, while others are protected and formalized. How and why is it that the law has come to designate slums as 'nuisance' and the residents of slums as a 'secondary category of citizens,' those that are distinguished from 'normal,' private property-owning citizens? It is through such designations that differentiated spatial value is produced and that space comes to be produced and regulated. Similarly, Holston (2007: 228) notes that Brazilian cities are marked by an "unstable relationship between the legal and illegal." While it may seem obvious and apparent that the urban poor are engaged in an informal and illegal occupation of land, much of the city itself is occupied through the 'misrule of law': "Thus in both the wealthiest and the poorest of Brazilian families we find legal landholdings that are at base legalized usurpations" (Holston, 2007: 207). Who then is authorized to (mis)use the law in such ways to declare

property ownership, zones of exception, and enclaves of value? (Yiftachel, 2009: 249–250) characterizes such processes as "the new politics of *gray spacing*" whereby subordinated groups are relegated to the "pseudo-permanent margins of today's urban regions, which exist partially outside the gaze of state authorities and city plans" while elite encroachers are allowed to colonize urban space.

What is at stake in such a genre of research is a relational understanding of urban informality. Yiftachel (2009: 250) correctly notes that gray spacing is "a ceaseless process of producing social relations." Such relationalities are starkly manifested in the territorial practices of the state. In fact, to describe urban informality as the production and regulation of space requires careful attention to the territorialized flexibility of the state. It is of course the state that determines what is informal and what is not, thereby generating an uneven geography of spatial value. It is the state that considers the informal subdivisions of corporate economies outside of Mexico City or Bangalore legal and formal while rendering illegal shantytowns in the same peripheries. It is the state that allows sprawling, elite 'farm houses' on the edges of Delhi to function legally as appendages of the agrarian land laws while criminalizing and violently demolishing slums and squatter settlements throughout the city. Such forms of state power often operate under the sign of 'public interest.' As Bhan (2009) demonstrates, judicial rulings seeking to assert the public interest have recently created a slate of slum clearances in Delhi. These rulings have hinged on judicial interpretations of encroachment that have likened the urban poor to illegal trespassers and thus as unworthy of legal and constitutional protection (Bhan, 2009: 139). Such forms of desubjectivation are not only expressions of punitive power but also the practice of distinction. Following Bourdieu (1979), distinction is the "judgment of taste" and thus the social practice of class power. It regulates the "economy of cultural goods" and produces an "aristocracy of culture" (Bourdieu, 1979: 1, 11). This social practice of class power is amply evident in the differentiated character of urban informality, or what Ghertner (2011) calls "rule by aesthetics." In his analysis of the production of space in Delhi, he shows how the judgment of taste determines which urban developments are granted amnesty, and even "heralded as monuments of modernity" (Ghertner, 2008: 66) while others are labeled "nuisance" and thus criminalized and demolished. Ghertner (2010: 185) thus argues that it is necessary to "expand our understanding of the epistemology of government to include attention to a more diverse array of governmental technologies, some more aesthetic than strictly calculative." This type of 'aesthetic normativity,' a phrase I borrow from Ghertner (2010: 199) is of course the mirror image of the aesthetic vision that marks 'jugaad urbanism' and its celebrations of the 'duct-taped ingenuity' of the informal city.

Frontiers: Informality and Capitalism's Future

In a profound and poetic intervention in the hegemony of capitalism, Gibson-Graham (2008) puts forward the call to "perform new economic worlds." Seeking to recover "diverse economies," they foreground "projects of economic autonomy and experimentation" (Gibson-Graham, 2008: 614). These projects include "squatter, slum-dweller, landless, and cohousing movements, the global ecovillage movement, fair trade, economic self-determination, the relocalization movement, community-based resource management, and others" (Gibson-Graham, 2008: 617). Such an "ontology of economic difference" (Gibson-Graham, 2008: 614) is potentially radical. But it also demands critical scrutiny. As Samers (2005: 876) notes, many of the diverse economies celebrated by Gibson-Graham are also informal economies. And these informal economies are in fact fully capitalized domains and often sites of intense exploitation. In fact, there is an uncanny resemblance between Gibson-Graham's postcapitalist utopias and the recent rediscovery of the informal sector by right-wing libertarians.

Perhaps, the most influential articulation of such a paradigm comes in the work of Hernando de Soto who presents informality as an economy of 'heroic entrepreneurs.' For de Soto, the Third World slum is rich in assets, albeit in the defective form of dead capital. The 'mystery of capital' is how such assets can be transformed into liquid capital, thereby unleashing new frontiers of capital accumulation. It is important to note that de Soto presents capital not as a relationship of production but rather as a 'representational process.' For him the poor are not workers but rather informal entrepreneurs who own assets, albeit those rendered impotent by faulty representation. 'Marx,' De Soto writes, "would probably be shocked to find how in developing countries much of the teeming mass does not consist of oppressed legal proletarians but of oppressed extralegal small entrepreneurs with a sizeable amount of assets." In de Soto's mediations, the diverse and alternative economies imagined by Gibson-Graham become new frontiers of capital accumulation.

In my recent work (Roy, 2010), I have designated these efforts to convert economies of poverty into frontiers of capital accumulation as poverty capitalism. In particular, I have drawn upon the case of microfinance to illustrate this process. Microfinance, the provision of financial services to the poor, is a highly popular poverty alleviation tool. Premised on the idea that the poor are inherently entrepreneurial, microfinance is an example of what I call "bottom billion capitalism," a set of dispersed but coherent efforts to construct, and make productive, a global economy where the world's bottom billion–the billion or so people living under conditions of poverty–are integrated into circuits of capital accumulation. This is what (Gates, 2008: 23) has called 'creative capitalism': "an attempt to stretch the reach of market forces … to bring far more people into the system – capitalism – that has done so much good in the world." Gates's vision is striking and seductive, for he is able to position poverty as not only the primitive other of the modern economy but also as its future. "There are markets all over the world that businesses have missed," he asserts (Gates, 2008: 27), and the poor constitute a particularly important and lucrative market, a 'billion bootstraps.' Put another way, informality, once the realm of deproletarianized survival, or imagined as an ontology of economic difference, is now the economy of bootstrap entrepreneurship, ready to be monetized and capitalized.

But such capitalization remains fragile. If nothing else, it remains subject to appropriations by the very informality celebrated by de Soto. These are diverse economies being

produced in the interstices of global capitalism, what Iquierdo (2012) calls "Capitalismo Amarillo" or "yellow capitalism." Documenting the activity of 'pirate traders' in the Tepito street market in Mexico City, Iquierdo traces circulations of mass-produced goods and 'original fakes' between Mexico City and the Special Economic Zone of Guangzhou, China. This is a counterfeit economy, one that belies the naïve populism of bottom billion capitalism as well as the romanticism of postcapitalist utopias. This is a thoroughly commodified and differentiated economy with a multiplicity of livelihoods and spatial strategies that would have seemed familiar to Keith Hart. Yet, it provides glimpses of tactics, appropriations, and disruptions, allowing subaltern informality to find a place in the world. This seems more convincing as an image of the future than the apocalypse of a planet of slums or a world of self-organized entrepreneurs.

Urban Internal Spatial Structure

Yan Song, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article defines the term 'urban internal spatial structure' and summarizes a schematic view of research areas related to urban internal spatial structure. Specifically, discussions are included of the observation of urban internal spatial structure, identification of driving forces of urban spatial structure, and investigation of the connection between urban spatial structure and a variety of outcomes, such as land and housing market performances, environmental safety and quality, and individual well-being.

Introduction

The term 'urban internal spatial structure' loosely encompasses dimensions such as urban development patterns, urban form, location of land uses, and location of firms and households. The way that urban spaces are arranged affects many aspects of how cities function and has implications for economic efficiency, accessibility, environmental sustainability, safety, social equity, and cultural creativity (Jacobs, 1961). For this reason, the subject has caught abundant attention by a variety of researchers. In recent decades, increasing public concern over the set of negative impacts of urban sprawl – the loss of open land resources, longer commutes, increased greenhouse gas emissions, and lower levels of physical activity – has led to policy efforts that seek to change the course of urban growth patterns. Notably, a range of urban and city planning efforts, such as the smart growth movement that emerged in the 1980s across the world, openly sought to avoid urban sprawl and improve public health through reshaped city forms, and to create good urban structures to help policymakers and the public choose desirable patterns of urban development. These movements still popularly appear in the dialog between research scholars, urban planners, policymakers, and the general public.

This article aims to summarize a schematic view of research areas related to urban internal spatial structure, including (1) observation of urban internal spatial structure; (2) identification of driving forces of urban spatial structure; and (3) investigation of the connection between urban spatial structure and a variety of outcomes, such as land and housing market performances, environment safety and quality, and individual well-being (Figure 1). The following sections synthesize main research topics and findings in each of these categories.

Figure 1 Research areas related to urban internal spatial structure.

Observation of Urban Internal Spatial Structure

The continuing efforts in creating efficient urban development patterns have brought increasing attention to the need for understanding urban spatial structures in order to describe patterns of development. Researchers and practitioners have developed numerous methods and focused on the development of detailed and policy-relevant measures to quantify urban spatial structures. The different types of measures of urban spatial structure are described in the following sections.

Monocentricity and Polycentricity of Cities

The most classical measures are monocentricity and polycentricity of cities or urban areas. As cities expand with prevalent usage of automobiles, there has been a higher level of urban decentralization, which is referred to the movement of population and businesses away from the established city center toward the urban fringe.

To measure decentralization, population and employment density gradients can be used. One example of a reliable estimation procedure of density gradient is the two-point estimation procedure. The estimates of density gradients can be made using available data on two areas: central city and total urbanized area. More specifically, the mathematical notation of the assumption that population density in an urban area declines as a negative exponential function of distance from the city center is $D(x) = be^{-ax}$, where $D(x)$ represents population density at distance x from the city center, b is the intercept (or the central density), and a is the density gradient of the function. A lower value in the density gradient indicates that an urban population or employment is more dispersed or spread out over the urban land area. For example, a value of 1.5 for the density gradient indicates a highly concentrated urban population or employment, whereas a value of 0.01 for the density gradient indicates a dispersed urban population or employment with equal density over the urban area.

Urban decentralization depicts two waves of urban expansion in the United States: decentralization of both population and employment. In the first wave of decentralization, which started in the late nineteenth century, the population moved to the suburbs. As late as in 1960, however, most jobs (63%) were still in the central city while 51% of the population lived in suburbs. In the subsequent second wave of decentralization,

jobs were also decentralized. By the year 2000, people both lived and worked in the suburbs in the United States. Across regions, the share of employment within three miles from the city center is rarely more than 19%. Consequently, employment subcenters emerged, establishing polycentricity of urban areas. Many studies have defined employment subcenters using a variety of methods, such as density maps, employment and population size, and minimum-density thresholds (Giuliano and Small, 1991). For examples, Giuliano and Small (1991) defined 32 employment subcenters in the five-county Los Angeles region by identifying a contiguous set of zones, each with 10 employees per acre, and with a combined minimum of 10 000 employees. Cho et al. (2008) identified subcenters for Mecklenburg County, part of the Charlotte metropolitan area in North Carolina. Because their study area is a much smaller metropolitan area than Los Angles (LA) in terms of population (its population is 6.58% of LA's), size (1.55% of LA's), and employment (10.35% of LA's), they lowered the minimum thresholds to four employees per acre for the employment density – that is, the mean employment density in the study area. As a result, a total of 10 subcenters, including the Central Business District (CBD), were identified in Mecklenburg County.

Similar decentralization patterns have been found in developing countries in recent decades. For example, Song (2013) investigates how road infrastructure in Chinese cities has shaped the degree of decentralization of Chinese urban regions in the last 20 years. There has been strong evidence that population density has been decreasing in the central city areas in Chinese cities. The improved mobility because of investments in road infrastructure, along with other factors such as increased urban income, has led Chinese cities to decentralize and evolve from monocentric to polycentric cities. It is evident that identification of population and employment subcenters can help understand the urban spatial structure of cities.

Metrics of Urban Internal Spatial Structure

There is a great amount of interest in extending the discussion of urban spatial structure by including measures of urban form. Understanding how land uses are organized within cities, for example, is essential for scholars and policymakers to tackle urban issues such as sprawl.

Galster et al. (2001) conducted a very detailed analysis of urban form with eight dimensions: density, continuity, concentration, clustering, centrality, nuclearity, mixed uses, and proximity. Each dimension reflects spatial relationships among units of analysis. These units are defined by assigning housing units from 1990 census blocks into 1-mile or 1/2-mile grids. Then, using Geographic Information System (GIS) tools, they computed each measure for 13 metropolitan areas. Finally, they normalized all the measures and, based on equal weights for each normalized measure, offered new and interesting information about urban development patterns in the US metropolitan areas. Consistent with conventional wisdom, Atlanta, Detroit, Miami, and Denver ranked high on the sprawl index while New York, Philadelphia, Boston, and Chicago ranked low. These measures developed by Galster et al. (2001) provide considerable information about forms of urban spatial structure beyond density and suburban population growth. Specifically, they reveal differences in spatial relationships among 1-mile grids within metropolitan areas and thus reveal quantitative insights about urban form. Yet their measures offer little of use to urban residents or policymakers. Should public officials in Houston, for example, be concerned or pleased that it ranked high in clustering and low in nuclearity?

Detailed and policy-relevant measures of urban form have since then been developed by many researchers. For example, Allen's measures, part of a planning support system called INDEX, include over 30 measures computed at a variety of geographic scales (Allen, 2001), offering a number of advantages over previous measures. Like all good indicators, they are well defined, relatively easy to compute when GIS data are available, easily interpreted, and policy relevant. Whereas gross measures of density, nuclearity, and centrality provide interesting information about metropolitan form, measures of transportation options, residential proximity to retail and industrial uses, and accessibility of parks, shops, and transit are of direct concern to citizens and policymakers. Furthermore, these measures serve well to evaluate impacts of market and planning on urban development patterns. Song and Knaap (2004) developed a variety of measures to illustrate urban development patterns in a range of urban areas in the United States. Their results suggest that some characteristics of development patterns differ significantly within and across study areas and over time; this raises doubt about the utility of one single index of urban spatial structure for an entire metropolitan area. Their results also suggest that by investigating characteristics of urban spatial structure, the good news is that density is getting higher, cities are becoming more compact, and neighborhoods are becoming more internally accessible; the bad news, however, is more extensive: residential neighborhoods are becoming more isolated, land uses remain separated, and pedestrian accessibility to various destinations is falling.

Despite the above-mentioned efforts in developing urban form metrics to quantify urban development patterns, there are several issues with current practice in computing measures. First, the set of measures included in one study sometimes do not sufficiently capture the complexity of urban form. Description of urban form relying on one-dimensional measures, like development density or land use, has failed to adequately describe urban form in a comprehensive manner. Thus there is a need for a set of metrics covering different dimensions of urban form. Second, some commonly used indicators are possibly ill-defined. As Talen (2003) writes, "too much discussion about cities is devoid of measurement … Examples are words such as suburb, public realm, mixed use, diversity and access. These concepts are vital to the discussion, but have been difficult to pin down." It is necessary to have better defined and measurable metrics, which can be either quantitative or qualitative. Third, more recently, the proliferation of spatial data sources and GIS tools for spatial data analysis has made a variety of new spatial metrics available. However, many of these computed spatial metrics are correlated and redundant measures. For example, when quantifying street network connectivity for cities, should we calculate the *Alpha* or the *Beta* Connectivity Index, or both?

In summary, there is a need for a set of better defined urban form metrics to depict urban spatial structure. Recent research on urban form calls for multidisciplinary approaches to measure urban spatial structure (Clifton et al., 2008). Four conclusions are drawn in this area of research. First, over the last two decades, substantial progress has been made in the ability to measure and analyze spatial patterns that help characterize urban form. Second, at multiple scales and for a variety of reasons, there are advantages to development that is mixed and compact. Third, normative principles and policies for addressing urban form need to be crafted at multiple scales and carefully designed to address the disparate issues that arise at each scale. Fourth, with so many disparate measures now used to operationalize the same constructs, it would advance urban form research to have some standardization in operational definitions and measurement protocols.

Built Environment Types within Urban Areas

More recently, researchers have developed quantitative methods of classifying and locating different types of urban developments within urban areas. In the past few years, urban designers have developed neighborhood typologies for the improvement of urban policy; the *transect* is a recent example. The central notion of the *transect* is a geographical cross-section of a region including a gradient of area types, ranging from rural to urban (Talen, 2002). Components of the built environment such as buildings, lots, land uses, and streets can then be organized into each area type. As shown in Figure 2, the rural-to-urban continuum can be divided into six discrete area types: natural, rural, suburban, general neighborhood, neighborhood center, and urban core. As one moves along the gradient of these area types, differences in design, ecology, and social structure are apparent. Policies used to manage urban development elements such as housing types, street design, and setback can be specified, using the *transect*, by each area type.

To apply the above described concept and to examine how different built environment types are allocated in the urban area in the rural-to-urban continuum in the US urban areas, Song and Knaap (2007) developed a method with the following steps: compute a range of measures of urban form, distill these into a small set of design factors using factor analysis, and develop statistically defined neighborhood classifications using cluster analysis. Variables associated with the physical form of the built neighborhoods have been established in the literature, as mentioned earlier. Street design, mixed land uses, accessibility, density, and alternative transportation modes are common variables used to identify neighborhood types (Song and Knaap, 2004). For examples, *street design measures* include number of intersections, number of cul-de-sacs, length of street miles, size of the street blocks; *lot design and density measures* include lot setback, size of the parcel, floor space of the single-family house, and number of single-family lots; *mixed land use measures* include acres of commercial, industrial, public, and multifamily land use; *accessibility measures* include distance to commercial stores or to bus stops; *natural environment measures* include acres of open space and amount of areas with tree canopy. Some of the above measures are highly correlated. The distribution of cul-de-sacs, for example, is highly correlated with the distribution of large blocks. Therefore, in the second step, it is useful to condense these variables into a smaller set of variables that removes redundancy and correlation in the data. Factor analysis, a technique for data reduction, can be used to understand the dimensional structure of the group of variables and improve the overall efficiency of the analysis. In the third step, cluster analysis, a method of combining observations into groups based on their similarity within a set of predetermined characteristics, can be performed to facilitate the identification of neighborhood types. K-means cluster analysis can be used to classify objects into different neighborhood types on the basis of similarities and dissimilarities in the values of the factors scores in such a way that each neighborhood type is internally as similar as possible but externally dissimilar to other

Figure 2 Urban transect. Source: http://www.transect.org/transect.html.

neighborhood types. The method has been applied to a range of metropolitan areas across the world to examine how urban developments within an urban area differ by their characteristics and locations. In what follows, there are two examples on identification of built environment types within urban areas in the United States and China, respectively.

In the rural-to-urban continuum in a typical US metropolitan area, there are in general, the following types of developments ranging from the outskirt to the central area.

Neighborhood Type 1: Sporadic Rural Developments

This type of development has a set of typically rural features: very sparse and unconnected transportation networks with poor access to transit, large lots and houses with low density, dominant rural land use with abundant open spaces but little mixed use such as public, industrial, or multifamily residential uses.

Neighborhood Type 2: Bundled Rural Developments

This type of development is poorly connected, dense with small lots, proximate to public land uses such as schools but not close to other land uses such as commercial and multifamily residential use.

Neighborhood Type 3: Outer Ring Suburbs

The outer ring developments are characterized by disconnected street networks, numerous cul-de-sacs, relatively large lots, predominantly detached single-family land uses with little nonresidential land use, and moderate amount of open space. These neighborhoods, developed in the decades after World War II, as developers began to add curvilinear street forms and new street block and lot layouts to the landscape, are the very image of mid- to late twentieth century automobile suburbs. In some cities, the outer ring suburbs, accompanied with concentrated employment centers, are identified as 'edge cities.'

Neighborhood Type 4: Composite Greenfields

Type 4 neighborhoods are located in recent greenfields and are characterized by modified grid and connective street networks, high density, moderate accessibility to bus stops, ample multifamily residential use but little commercial land use in the immediate neighborhoods.

Neighborhood Type 5: Downtown, Inner and Middle Ring Suburban Redevelopments/Infill

Type 5 developments, which are located in downtown areas or at the inner and middle ring of cities, are characterized by connective street networks and small street blocks, small lots and high density, accessible bus services, mixed land use such as commercial and multifamily residential use, but little open space. These neighborhoods correspond to the mid-nineteenth and the early twentieth century developments. The homes in downtown areas were built in the late eighteenth and early to mid-nineteenth centuries and had characteristics such as grid street networks and small, square, and 200-foot blocks. These small blocks were developed by the prewar land developers to maximize the rent received from higher-priced corner lots – the smaller the blocks, the more corners to rent per land claim. In response to the advent of streetcars, neighborhoods developed in the 1870s and 1880s had larger rectangular blocks and shops along streetcar corridors. From the 1930s, when the widespread use of automobiles was added to the settlement pattern of earlier years, the inner and middle suburban neighborhoods began to show a modified rectilinear grid with blocks of varying sizes.

Similar analysis has been done to identify built environment types in developing Chinese cities (Zhang and Song, 2013), demonstrating a variety of five built environment types based on variations in the built environment measures. These five neighborhood types also depict a continuum from urban and suburban areas to rural areas. Three main themes are identified for developing Chinese cities: the renewed urban area, the decentralized suburbs, and the urbanizing rural area. More specifically, type 1 neighborhoods are the urbanizing rural neighborhoods, featuring low density, poor transport connections and commercial or occupational linkages, and reflecting a new transformational force in many rural neighborhoods, where urbanization is motivated by the conversion of farmland into medium- to small-sized industrial factories. This transformation can increase landowners' income and absorb surpluses in the local labor force. Types 2 and 3 neighborhoods, the new urban fringe and the expanded urban neighborhoods, respectively, are suburbanized area types that were once greenfields. Mostly thanks to market forces (such as increased income and demand for new and bigger housing units) and planning efforts, the new urban fringe neighborhoods have now developed into lively urban places with moderate population density, high accessibility, and high land use diversity. Driven by employment and population decentralization, these suburbanized districts are now acquiring an urban feel as streets are paved, public spaces are beautified, and housing increasingly takes the form of high-density, multistory apartment buildings. Types 4 and 5 neighborhoods, the renewed urban core and the urban district neighborhoods, respectively, are clearly gentrifying. This process is likely attributed to the urban renewal movement motivated both by the marketplace and by the government policies, which are enforced to redevelop the deteriorated old, public, and welfare housing into high-end or moderate commercialized housing and core business uses; and to upgrade street networks and transit service.

Formation of different built environment types within urban areas is driven by the joint forces of government policies and the marketplace. In the case of Chinese cities, the city core is quite vibrant with housing and commercial rehabilitation in the core area, due to cultural preferences, market forces, and government policies. The role of the state in China has been more direct and powerful in setting the suburbanization process and urbanization process of rural areas in motion. Among the forces driving suburbanization were marketization of urban land, the shift of industrial land to tertiary use, state and local funding of transportation improvement, the availability of foreign and domestic capital, and new housing construction in the suburbs. The government policies have also been active in promoting the construction of the 'New Countryside' in rural areas, aiming to decrease the discrepancies between urban and rural living conditions.

From these two examples, it is evident that identifying different built environment types within urban areas facilitates our understanding of the internal structure of urban areas, which further assists with drafting relevant and varied urban policies for different types of neighborhoods within urban areas.

Types and Quantity of Land Conversions

Identification of urban internal spatial structure also involves the detection of land use conversions; that is, land use changes resulting from converting a vacant plot or changing the current use of a given land parcel. Some typical land use classifications include (Wu and Yeh, 1999) agricultural, industrial, commercial (including large department stores, offices, hotels, markets, and recreation facilities), residential development, government, institute, and community facilities.

To identify land conversions, one method is to conduct a supervised classification of Landsat satellite imagery and detecting change in urban areas. Landsat is a commonly used data source for analyzing landscape change. It has global coverage and captures data in seven bands, at a resolution of 30 m, in scenes that are approximately 180 km^2. Landsat five and Landsat seven detect blue, green, and red light in the visible spectrum as well as near-infrared, mid-infrared, and thermal-infrared radiation that human eyes cannot perceive. Landsat records this information digitally and it is downlinked to ground stations, processed, and stored in a data archive. By classifying the patterns of reflectance in each grid cell, researchers can interpret the land cover located there and once satellite images have been classified into land cover categories, researchers can study how those categories change over time. Typical steps involved for detecting land use changes include the following: (1) creating and preparing a training dataset to support the satellite image classification; (2) deriving a signatures file containing spectral characteristics of land cover classes of interest; (3) performing a supervised classification of Landsat satellite imagery; and (4) detecting and quantifing the observed changes in urban areas over time.

Numerous studies have been carried out to detect land use changes within urban areas. By detecting the amount, type, and location of land use conversion patterns, researchers are able to evaluate how the structure of urban areas changed over time. For example, by examining the changing urban landscape patterns between 2001 and 2006 for the United States using the land cover data from the US Geological Survey, Kaza (2013) characterizes the landscape metrics for each county in the continental United States. He found uneven and heterogeneous patterns of growth across counties. More importantly, his study shows that although urban counties are becoming less fragmented, some rural counties in the Southern and Western United States are experiencing significant leapfrog development. Land conversion studies can also be carried out for single urban area or metropolitan regions. For example, Song (2013) tracks land use changes from nonurban to urban use by each cell of 30 by 30 m for the City of Shenzhen, China. The land use change analysis yielded a total of 8.2% of the cells that changed between 1994 and 2005. The spatial distribution of changes is shown in Figure 3. Most changes occurred along the coastline and highway or arterial corridors.

A second method is to analyze land parcel changes by comparing parcel shape files in successive periods to determine whether they had split or changed functions (Wilson and Song, 2011). GIS shape files over time are necessary for such an analysis. ArcGIS software and the Python scripting language can be used to automate and streamline spatial data processing and manipulation tasks.

In general, recent land conversion studies have demonstrated that urban sprawl has been occurring, thus calling for public policies designed to reverse the trend and correct for negative externalities brought about by urban sprawl.

Identification of Driving Forces of Urban Spatial Structure

Many studies have focused on identify driving forces (including both market and regulatory factors) shaping urban development patterns, such as urban scale, and rate and location of land use conversions. For example, researchers have used standard monocentric city models (both closed city and open city models), and extended monocentric city models to investigate the determinants of urban spatial scale of urbanized areas across the world (Ke et al., 2009; Song and Zenou, 2006). Theoretical models define that four basic factors – population, income, commuting cost, and price of rural land – explain variations in urban spatial scales. Empirical analyses of cities across the world confirm the theoretical derivations with the following results. For the US cities, the population and income variables have positive and significant effects on the spatial size of urbanized areas; the expenditure on transportation, a proxy for commuting costs, has positive effect on urban spatial scale and thus confirms the predicted negative relationship between urban size and commuting costs; and the higher agricultural land rents surrounding urban areas can result in smaller cities in the United States (Song and Zenou, 2006). Other studies (Ke et al., 2009) have shown strong evidence that urban economics theory has common value in explaining urban spatial scale in different countries, provided that market forces are not suppressed.

Another set of studies confirmed that the decision to convert undeveloped land or to change (usually to intensify) the existing use is influenced by a variety of economic, social, political, and personal considerations. Sheer population growth increases the absolute demand for housing and other developed land uses, and demographic changes (e.g., an influx of young professionals) can impact the types of residential development that are favored. The type and magnitude of economic activity can, therefore, exert a great deal of influence on the number and characteristics of the local population. The political climate also impacts the nature of regulation and extent to which growth management policies are implemented to affect land conversion processes. In addition to leadership at the regional and state levels, a robust economy and an educated population are key correlates of planning and development management influencing land conversions (Wilson and Song, 2011).

A variety of techniques, including hazard models and discrete choice models, have been employed to study the conversion of land uses. For example, Bockstael (1996) brought together concepts from several disciplines to model the probability of land parcel conversion within the Patuxent watershed in Maryland. The key contribution of this study was its representation of the landowner's decision to convert a given parcel from one state (use) to another as a comparison of the present value of expected returns under the current state less the costs of converting the parcel now, and the expected returns under alternate states minus conversion costs. Zax and Skidmore (1994) used a hazard model to investigate the effect of tax rate changes on the probability of parcel conversion and found

Figure 3 Land use changes between 1994 and 2005 in Shenzhen. Source: Author.

evidence that when increases in the tax rate are known in advance, the effect is an increase in the short-term probability of development. Wilson and Song (2011) analyzed parcel changes and then conducted a spatially explicit hazard analysis of land use change in Mecklenburg County in North Carolina in the United States, to identify a set of factors that predict which vacant land parcels are most likely to be subdivided during a given one-year time period. They found evidence of a positive association between large residential subdivision events and an increased likelihood of subsequent subdivision activity. This corroborates that major residential subdivisions drive land conversion.

As the examples illustrate, by understanding the factors that explain land conversions, planners, elected officials, and researchers can be in a stronger position to manage growth, craft public policy, and refine our understanding of how urban systems function.

Investigation of Urban Internal Spatial Structure and Associated Outcomes

Investigation of the connection between urban spatial structure and outcomes encompasses a range of topics. For example, there are a variety of studies on how alternative urban forms (monocentric versus polycentric, or compact versus sprawling) are valued in a land or housing market, whether there is any relationship between alternative urban forms and individual well-being (such as commuting time and level of satisfaction), and whether alternative urban development patterns in the long term can affect water and air quality.

To explore how alternative urban forms (compact versus sprawling) are valued in a housing market, quantitative price valuation of alternative urban forms can be performed. Spatial hedonic housing models are used to evaluate how certain features of urban development patterns, such as density, connectivity, land use mixture, and accessibility are valued in a housing market (Song and Knaap, 2003). The results have shown in general some price premium associated with more compact developments with a range of amenities, such as access to public transit, neighborhood stores, and parks.

Many studies explore the relationship between urban spatial structure and individual well-being. For example, Cho et al. (2008) explored how polycentric urban spatial structure affects residential location choice and they find that access to certain employment subcenters, measured in terms of generalized cost, is an important determinant of household residential location decisions and thus brings a higher level of utility to the households. Other research questions include, for example, would monocentric or polycentric spatial structures result in different commuting behaviors? How would different spatial structures result in different

outcomes in resident satisfaction, physical activity, or stress levels? More research is needed in these areas.

Scholars have also explored whether alternative urban forms (compact versus sprawling) can affect air quality in the long run. Integrated land use–transportation–emissions models have been developed to test, for example, whether polycentric and transit-oriented developments can reduce the vehicular emissions contributing to tropospheric ozone and to fine particulate matter. One example of this area of research developed a modeling system assessing long-term development scenarios for Charlotte and Mecklenburg County, North Carolina's largest metropolitan area and part of an ozone nonattainment area. The results demonstrate that more efficient urban spatial structure can result in reduced emissions and subsequently improved air quality (Morton et al., 2007). Nevertheless, research in this area is still scarce, more studies using different methods, such as simulation modeling or regression analysis using empirical data, are needed to explore what form of urban spatial structure can make cities more green and healthy.

In conclusion, the term 'urban internal spatial structure' encompasses many related dimensions, including a range of concepts concerned with the organization, configuration, and form of urban land use and activities. The way that land use and activities are arranged affects many aspects of how cities function and has implications for economic efficiency, accessibility and connectivity, social equity, and environmental sustainability. When most cities around the world are urbanizing or suburbanizing, a shift to a sustainable urban spatial structure for urban areas provides a more desirable growth path.

Abstract

Urban environments are complex with many constituents. Likewise, health is multidimensional. Hence, both these subjects are not structured within traditional disciplines and professional sectors. Therefore, urban life and health ought to be considered in terms of the multiple factors that influence living conditions and health status, as well as the interrelations between them. An ecological perspective recognizes that behavioral, biological, cultural, economic, social, physical, and political factors need to be considered if a comprehensive understanding of urban health is to be developed and applied. In order to integrate all these dimensions, it is necessary to go beyond interpretations that rely solely on the biomedical model of health. Interdisciplinary and collaborative research contributions are necessary.

Introduction

One hundred years ago, about 80% of the world's population lived in rural areas, whereas in the year 2008 a half of the global population lived in cities. The twentieth century was characterized by a growth in the number, population size, and total surface area of cities on a scale previously unknown, and this trend is expected to continue during the twenty-first century. Some have argued that the last century corresponded to a period of 'the urban revolution' that has transformed the physical, psychological, and social dimensions of daily life including housing, transport, and other characteristics of metropolitan areas. Urban life has important health benefits including easy access to job markets, education, health care, medical services, as well as diverse cultural and leisure activities (Lawrence, 2000). However, at the beginning of the twenty-first century, urban health can be characterized by relatively high levels of tuberculosis, respiratory and cardiovascular diseases, cancers, adult obesity, and malnutrition, tobacco smoking, mental ill health, alcohol consumption and drug abuse, sexually transmitted diseases (including AIDS), as well as fear of crime, homicides, violence, and accidental injury and deaths. It is noteworthy that in the 1990s, mental ill health was integrated into the etiology of urban health, and that the promotion of physical and mental health was accepted as a complementary goal for national and local policymakers and professionals.

What Is Urban Health?

The World Health Organization (WHO) states that health is "not merely the absence of disease and infirmity but a state of optimal physical, mental, and social well-being" (World Health Organization, 1946). This definition is idealistic, but it has the merit of not focusing on illness and disease, which have often been considered as either temporary or permanent impairment to health, or the malfunctioning of a single or several constituents of the human body. Given that the WHO's definition of health includes social well-being, the most common interpretations of health ought to be enlarged. The WHO also states that the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political, economic, or social condition.

Health can be defined as a condition or state of human beings resulting from the interrelations between humans and their biological, chemical, physical, and social environment. All these components of residential environments should be compatible with their basic needs and their full functional activity including biological reproduction over a long period (Lawrence, 2001). Health is the result of both the direct pathological effects of chemicals, some biological agents, and radiation, and the influence of physical, psychological, and social dimensions of daily life including housing, transport, and other characteristics of metropolitan areas. For example, improved access to medical services is a common characteristic of urban neighborhoods that is rare in rural areas. In the field of health promotion, health is not considered as an abstract condition, but as the ability of an individual to achieve her or his potential and to respond positively to the challenges of daily life. From this perspective, health is an asset or a resource for everyday life, rather than a standard or goal that ought to be achieved. This interpretation is pertinent because the environmental and social conditions in specific residential environments do impact on human relations, induce stress, and can have positive or negative impacts on the health status of groups and individuals (Hartig and Lawrence, 2003). It also implies that the capacity of the health sector to deal with the health and well-being of populations is limited and that collaboration with other sectors would be beneficial.

A discussion of urban health should begin by clarifying what is meant by urban and what interpretation of health is applied. Although there is no consensus about the definition of 'urban,' which varies from country to country, the United Nations uses national definitions that are commonly based on population size. Many countries use 10 000 resident persons as a benchmark to define urban, whereas other countries including India use 5000 persons as the referent. Other definitions of urban are based on the administrative or political

authority of municipalities, especially the degree of autonomy in relation to the national or state administration. Other definitions include the socioeconomic status of the resident population, especially their livelihood (e.g., the share of all employed persons having nonagricultural occupations). A combination of these characteristics could be used to interpret rural and urban areas, but this has been rare, especially in recent published research on the health of urban populations.

Urban health is a vast and complex subject. In order to understand the multidimensional nature of urban health, all the constituents of urban ecosystems and the interrelations between them should be considered over time. These constituents include four interrelated sets of hazards:

Environmental hazards including ambient air quality, ambient noise levels, soil and water contamination, and solid waste disposal.

Social hazards including criminality, violence, and community discord, as well as the lack of education and training especially for immigrants, women, and children.

Economic hazards such as no affordable housing, permanent unemployment, or inequalities of access to diverse kinds of resources including primary health care.

Technological hazards including traffic accidents, industrial and chemical disasters on industrial sites, and contamination from mass-produced foods and synthetic products.

These four main sets of risk factors are variable within and between urban areas and neighborhoods and even the specific characteristics of buildings impact on health. In addition, exposure to hazards can vary over short and relatively long periods of time. For example, the internal conditions of a room in a housing unit may be related to the physical condition of the residential building and its site, and the urban neighborhood in which it is located. In turn, the neighborhood, the city, the region, and the country are all directly or indirectly interrelated. Hence, global challenges, including climate change, can have different impacts on cities and urban neighborhoods within cities, depending on their geographical location, local climate, infrastructure, and building construction (McMichael, 2000). In essence, local and international levels are linked across cultural, geographical, political, and temporal boundaries.

The exposure of different population groups (e.g., children, ethnic groups, the elderly, and the unemployed) to these four sets of risk factors should also be taken into account (Galea and Vlahov, 2005). It cannot be assumed that an individual, household, or a particular social group exposed to one or more of the above sets of hazards will necessarily suffer negative impacts to their health. In principle, biologically inherent mechanisms are mediated by the social and environmental circumstances of residential neighborhoods (Hartig and Lawrence, 2003). Hence, someone exposed to a hazard can have a different risk or negative impact compared with another person also exposed to the same hazard. Therefore, it is necessary to interpret the health of urban populations in terms of both individual and social differences by explicitly accounting for age, gender, socioeconomic class, occupational status, and the geographical and temporal distribution of the population in terms of the four sets of risk factors presented above.

An ecological interpretation of urban life and health considers four main sets of interrelated factors: the individual, who has a specific genetic code with a susceptibility and immunity to illness and disease, as well as lifestyle traits; the agent or vector of illness and disease, including not only biogeophysical components of the environment but also the social and psychological dimensions of human settings; the physical and social environment of the individual that affects the susceptibility of the host, the virulence of biophysical agents, and the exposure, quantity, and nature of the contact between host and vector; and the available resources used by the individuals and households including housing, nutrition, money, information, and access to health and medical services, which ought to be affordable for all groups of the population. This perspective implies that an analysis of the interrelations between multiple components of any human ecosystem is necessary. Systemic interpretations of human illness, health, and local environments have a long history. They can be traced back at least as far as the Hippocratic treatise 'On Airs, Waters, and Places' published initially about 2600 years ago (Hippocrates, 1849).

The distinction between biomedical models and ecological interpretations of urban health is fundamental. The germ theory, for example, is an incomplete explanation of human illness and disease because it ignores the contribution of numerous physical and social dimensions of the environment that can impact on health. Ecological interpretations maintain that the presence of a germ is a necessary but not a sufficient condition for an individual to become ill. They accept that some individuals become more susceptible to certain illnesses because of their differential exposure to numerous environmental, economic, and social factors that can promote or be harmful to health and well-being. This interpretation does not ignore the influence of genetics, individual behavior, or primary health care. However, it maintains that, alone, these do not address possible relations between social problems and illness (e.g., inequalities) or positive social dimensions and health promotion (e.g., public education). The distinction between potential and actual health status can be the foundation for a new interpretation of health that includes the way environmental, economic, social, and technological risk factors transgress traditional disciplinary boundaries while remaining locality and temporally specific. Cues for this interpretation were already provided by human ecologists in the 1920s.

The early studies in human ecology at the University of Chicago plotted the geographical distribution of some characteristics of the resident population of Chicago including their ethnic origin, socioeconomic status, birth and mortality rates, delinquency, mental, and other illnesses. These cartographic studies enabled the authors to overlay the maps of the spatial distribution of these characteristics in order to identify those that occurred in the same urban area. This approach established many correlations (Park et al., 1925). For example, the distribution of cases of tuberculosis corresponded with the highest incidence of delinquency. This finding led the authors to suggest that cities comprise 'natural' areas that are defined geographical, economic, social, and cultural dimensions. The term 'natural' was used because these areas were not planned but constituted as the city developed. Each 'natural' area is characterized not only by its geographical location but also by

the market price of land and property, and sets of customs, norms, and nonmonetary values that are part of the lifestyle of the residents.

The first generation of studies in human ecology from the 1920s marked a growing interest in collaboration among researchers from disciplines who worked to deal with complex multidimensional questions including those of urban health. This kind of interdisciplinary collaboration has been extremely fruitful since the 1970s.

Research on the impacts of the activities of human societies on biophysical components of the biosphere and on humans themselves has been completed (Boyden, 1992). This research examines the adaptation processes used in response to changes in human ecosystems. The term ecodeviation is used to refer to a general biological principle that describes life conditions of human and other species that are different from those in the natural habitat of the species. When these differences become large, sudden perhaps irreversible behavioral and physiological maladjustments may occur (Laughlin and Brady, 1978). Some physiological maladjustments during the last 10 000 years include diseases such as scurvy, typhoid, cholera, smallpox, and influenza.

Another approach used by Boyden and his colleagues analyzes the advent and acceptance of new technologies including those that are not essential for basic human needs and sustenance. These inventions become an integral part of human societies by a process termed as technoaddiction. The spatial and social organization of societies can become dependent on them as shown by the reliance on combustion engines using fossil fuels. For example, this has led to transportation policies in many countries based heavily on road traffic using private cars in preference to public transport by rail. Some consequences of this kind of technoaddiction include the extensive use of arable land for urban and regional development, the incidence of air pollution and noise, as well as nonactive lifestyles.

An in-depth case study of Hong Kong illustrates the principles of ecodeviation and technoaddiction. This case study was completed as part of the UNESCO Man and Biosphere Program dealing with ecological studies of human settlements (Boyden et al., 1981). The case study of Hong Kong by Boyden and his colleagues identifies and measures the changing ecological characteristics of the human settlement and its hinterlands prior to the formal founding of the British Colony in 1842 until the 1970s. This study notes that with the advent of colonialism traditional rules and customs were challenged by foreign ones leading to the introduction of novel forms of land tenure, new resources including materials, machinery, and techniques, and the proliferation of cash and market economies. The specialization of tasks in Hong Kong increased. The economic consequences of these kinds of changes are important, because the total cost of energy consumption, materials, and labor increased.

This case study examines patterns of energy production and consumption flows, the production and disposal of wastes including pollutants, the densification and dispersal of the built environment, and impacts on the health and well-being of the population. The case study also includes a comparison of traditional Chinese and contemporary imported methods of food production, processing, and packaging. The outcomes of the change from one set of process to the other include impacts on land uses, agricultural production methods, the import and export of diverse kinds of materials, and the diet and health of the population. The authors note that, at the beginning of the twentieth century, inadequate nutrition was common in Hong Kong owing to a diet almost exclusively limited to polished rice. By the late twentieth century, however, the local environment provided a range of food including fresh fruit, fish, meat, and vegetables. Although nutritional diseases, such as beriberi, have been eradicated, in recent decades there have been changes in the diet of the population especially the increasing consumption of refined carbohydrates (e.g., white flour and refined sugar), which imply reduced dietary fiber. These changes can lead to increased dental caries, overnutrition, and obesity, as well as an increase in diabetes. The authors note that the death rate from diabetes was 4.3 per 100 000 in 1974, which is a threefold increase since 1961 and a fourfold increase since 1949.

Boyden and his colleagues raise many questions about the costs and benefits of industrialized food production, the toxicity of fertilizers, the ecology of soil and water catchment areas, and deforestation. In essence, this kind of case study can identify both the intended and unintended consequences of human products and processes over the long term. It also shows that it is important to distinguish between the tacit know-how of the local population prior to colonization (in which knowledge and practice are indistinguishable) and the explicit know-how of the colonial administration (in which theory and practice are interrelated but clearly distinguishable). The gradual suppression of implicit instruments of regulation by a growing number of explicit ones has occurred with urbanization in Hong Kong and elsewhere. This example illustrates that there is a need to reconsider both implicit and explicit regulatory means and measures, which are fundamental constituents of people–environment relations.

What Is a 'Healthy City'?

According to Hancock and Duhl (1988), "a healthy city is one that is continually creating and improving those physical and social environments and expanding those community resources which enable people to support each other in performing all the functions of life and in developing themselves to their maximum potential." This definition of a healthy city implies that health is determined by both short- and long-term processes. A healthy city is not only a quantified outcome such as the measurement of health status of the population. The long-term goals of the WHO Healthy Cities project are to integrate health in the agenda of all policy decision makers in cities, to create a strong partnership for health promotion between groups in the public and private sectors, and to apply a local, participatory approach when implementing projects (Goldstein, 2000; World Health Organization, 2000).

The health status of populations in specific urban areas is the result of not only many material and nonphysical constituents listed in **Table 1** but also the interrelations between them. Therefore, it is inappropriate to isolate one factor from the contextual conditions in which it occurs. Instead, systemic ecological approaches ought to be applied to understand both

Table 1 Qualities of a healthy city

1. The meeting of basic needs (for food, water shelter, income, safety, and work) for all citizens
2. A clean, safe physical environment of high quality, including housing quality
3. An ecosystem that is stable now and sustainable in the long term
4. A diverse, vital, and innovative economy
5. A strong, mutually supportive, and nonexploitive community
6. A high degree of participation and control by the public over the decisions affecting their lives, health, and well-being
7. The encouragement of connectedness with the past, with the cultural and biological heritage of city dwellers, and with other groups and individuals
8. Access to a wide variety of experiences and resources with the chance for a wide variety of contact, interaction, and communications
9. A built form that is compatible with and enhances the preceding characteristics
10. An optimum level of appropriate public health- and sick-care services accessible to all
11. High health status (high levels of positive health and low levels of disease)

the factors and the interrelations between them. It is recommended that although social scientists, psychologists, and medical or public health researchers have not often collaborated, there are good reasons for them to share experience and apply interdisciplinary approaches.

The 11 qualities of a healthy city listed in **Table 1** need to be understood and applied in specific localities using innovative empirical research and professional practice. This stems from the fact that many contributions that are meant to address health promotion and prevention have not been wholly successful even though many urban planners, public health officers, and medical practitioners are convinced that they have the 'right answers.' There is an urgent need for innovative approaches to address the continuing failure of the wealthiest countries of the world to provide all citizens with secure employment, affordable housing, and appropriate health care that meet at least minimal requirements. The failure of so-called 'model' housing estates and urban planning projects constructed in the 1960s and 1970s in numerous cities around the world clearly shows that new ideas, working methods, objectives, and criteria are needed (Burridge and Ormandy, 1993; Halpern, 1995).

Our incapacity to deal with the above-mentioned problems is related to the complexity of dealing with urban health, the compartmentalization of scientific and professional knowledge about urban ecosystems, the bureaucratic division of responsibilities in cities, and the increasing diversity of living conditions between various cities and within specific cities. In addition, the lack of effective collaboration between scientists, professionals, and policy decision-makers has led to the 'applicability gap' in sectors that deal with urban planning, public health, and many other sectors concerned with the construction and maintenance of cities. These shortcomings of mainstream scientific research and professional practice are not necessarily the result of the lack of political commitment, financial resources, or viable propositions. They are, above all, the logical outcome of the narrow vision of so-called experts who do not address fundamental issues but only topics isolated from their urban context.

In order to deal with these limitations, at least four sets of obstacles need to be overcome. First, those conceptual frameworks that do not recognize the pertinence of an ecological interpretation of urban health and living conditions need to be challenged. Second, those methodological contributions that value rational, quantified interpretations of illness and disease at the expense of qualitative interpretations of health and well-being need to be replaced by more holistic research. Third, the segmentation and bureaucratization of professional knowledge and expertise often at the expense of the experience of laypeople should be challenged. Finally, the philosophy and conceptual framework for the education and training of professionals and scientists is too shortsighted. Some of these shortcomings are being addressed by the WHO Healthy Cities project in order to promote health and well-being of citizens.

The WHO Healthy Cities Project

The Healthy Cities project was founded in 1987 by 11 European cities and the WHO Regional Office for Europe. Today, there are more than 30 national and regional networks in Europe involving about 600 municipalities, now complemented by many hundreds more in each of the regions of the world (Goldstein, 2000). The Health for All strategy provides the strategic framework for this project. The Healthy Cities project in the WHO European region includes four main components. First, the designated cities are committed to a comprehensive approach to achieving the goals of the project. Second, national and subnational networks together with Euronet facilitate cooperation between partners. Third, multi-city action plans are implemented by networks of cities collaborating on specific issues of common interest. Finally, special (model) projects are being implemented in Central and Eastern Europe.

The Healthy Cities project involves collaboration among sectors by formulating a 'City Health Plan' that identifies the interrelations between living conditions in urban areas and the health of the residents (Green et al., 2003). It is argued that health can be improved by addressing the physical environment, and the social and economic determinants of health in all situations (such as the home, the school, the workplace). This broad interpretation has meant that equity and social inequalities are identified as key factors in cities that need to be addressed. In particular, the plight of vulnerable social groups (including the handicapped, homeless, unemployed, single mothers, and street children) is ranked as a high priority for interventions. This approach is meant to focus not only on specific groups but also on particular neighborhoods where there are concentrations of vulnerable people with relatively high health risks.

Supportive Environments

The concept of supportive environment has been used in the Healthy Cities project to emphasize that policy definition and implementation should focus on all the determinants of

health, not just those within the health sector (Bistrup, 1991). Therefore, it includes the role of physical environmental factors that influence health and not just the lifestyle of individuals and groups in specific localities. In addition, it is not limited to the physical characteristics of the environment because it accounts for the cultural, social, economic, and political dimensions. When these dimensions are explicitly addressed then it is necessary to deal with equality and equity in societies and how these impact on health and well-being in precise residential environments.

From this perspective, the layout, design, and maintenance of residential environments should meet the requirements of all groups of the population including the increasing number of people with special needs, in particular, the most vulnerable in society: for example, the homeless, a group that comprises an increasing number of adolescents and young adults in industrialized countries; the elderly who need domiciliary care; people with disabilities who require easy access to and within housing units; single-parent households that may need access to special child care services; and refugees and immigrants that have specific cultural customs in and outside their housing unit that should be accommodated. This suggests that an integrated, interdisciplinary understanding of how the health of populations in precise localities can be improved is essential if a range of interventions are to be applied effectively again at the beginning of the twenty-first century.

An interesting example of the application of this approach is public transport in the region of Zurich, the largest city in Switzerland. This region accommodates 1 million residents. The public administration has implemented government policies to promote public transport at a lower economic and ecological cost than reliance on private motorcars. Public transport is more energy efficient and less polluting than private motorcars, especially when electric motors are used for trains and trams. Public transport uses less land surface area per passenger than the roads and car parking required for private motorcars, thus conserving natural landscapes and sites for allotments and leisure activities. Since the implementation of this policy in the 1980s an electric train network has been coordinated with tram and trolley bus routes so that a person has access to all neighborhoods in the region without the need to use a motorcar. The implementation of this coordinated transport policy in the Zurich region has led to a substantial increase in the use of public transport from 363 journeys per person per year in the 1980s to 532 journeys per person per year in the 1990s.

During the same period, the city administration implemented plans for diverting road traffic from residential streets to main roads and converting some of these streets into pedestrian zones with landscaping and children's playgrounds. In addition, new residential neighborhoods have been consciously planned with medium- and high-density residential buildings and other functions that are accessible for pedestrians in the region who can use public transport. The environmental, economic, health, and social impacts of this vast coordinated policy should not be underestimated. The coordinated transport project in Zurich shows the wide range of benefits of collaboration spanning across several sectors and explicitly dealing with health in tandem with the qualities of the local residential environment. It stems from a critique of piecemeal approaches to road transport, car parking, and traffic safety. This coordinated approach across several sectors reinterprets accessibility and mobility in and between urban areas in terms of not only public and private modes of transport but also air and noise pollution, consumption of nonrenewable resources, monetary costs and public investments, active and sedentary lifestyles, as well as health and well-being. This ecological approach not only raises questions about the high priority attributed to private motorcars during the twentieth century but also shows that direct investments in efficient public transport systems and pedestrian precincts can also be considered as indirect investments to promote environmental quality, reduce energy consumption and air pollution while promoting health-promoting behavior (physical activity by walking and cycling) and human well-being.

Conclusion

Today, policymakers in most countries still have great difficulty in measuring, describing, and explaining constancy, change, and differences in health, housing, and environmental conditions in cities. Part of the difficulty has been the lack of systematic data collection (Lawrence, 1996). A dynamic set covering several sectors is required across a range of administrative levels and geographical scales. Alone, official statistics based on national census returns do not provide comprehensive accounts of the quantity and quality of the housing stock, urban infrastructure, and services in rapidly developing urban areas and they ignore illegal buildings in informal settlements. Today, there are several kinds of innovative techniques and tools that can be used to monitor and analyze the spatial distribution, dynamics, and interrelated nature of environmental, housing, demographic, and health profiles in urban areas. There have been significant developments in the collection and interpretation of data, indicators, and information during the 1990s that warrant further systematic applications. For example, geographical information systems can represent data from diverse sources (including remote sensing) in order to identify relationships between the represented components of urban areas. This relatively new approach has not been widely applied in the health sector in many countries, but its use to monitor ambient environmental conditions, the built environment, and the incidence of ill health and disease warrants a commitment from public administrations at both national and local levels.

Evidence on the determinants of health of urban populations has increased since the 1990s, especially in relation to the socioeconomic inequalities of people living in urban areas. Nonetheless, too little attention has been given to assessing the effectiveness of interventions to change these determinants in specific localities and monitor the outcomes on health. If these evaluations are not available, then policy decision-making is handicapped. More research is required to evaluate different kinds of interventions that improve the built environment in urban areas in order to identify impacts on health and well-being by the collection of time series data. Environmental impact assessment, health impact assessment, and cost–benefit analysis can be used to study interventions that are meant to promote health. Today, there are too few studies that evaluate

different approaches for the communication of information to inform and educate laypeople, even though, studies show that the health impact of water supply and sewage disposal is influenced by the way the population uses (or misuses) new infrastructure and services. In addition, this research can identify economic, cultural, and political barriers to change. An understanding of the political feasibility of policy options should include an account of these barriers, as well as the legal framework and the behavioral norms and values of the population.

Urban Life: Future Developments

MA Hughes, University of Pennsylvania, Philadelphia, PA, USA

This article is reproduced from the previous edition, volume 24, pp. 16029–16031, © 2001, Elsevier Ltd.

Abstract

The future of urban settlements, as was their past, will likely be driven by three fundamental mechanisms. First, the changing technology of the digital economy will reshape the possibilities of urban life over the next generation. Second, the limits of post-1945 development patterns, especially the low density suburban form prevalent in the United States for 50 years, will be tested. Third, the attractive power of centers will wax or wane; given the diminished power and autonomy of the large industrial urban center over the preceding century, this third mechanism is likely to be closely related to changes in the first two. The multiple contingencies of these and other mechanisms will frame the important issues facing decision makers over the coming decades. Three are already apparent. First, if largeness is a consequence of a passing industrial era, then how will the more fundamentally urban quality of density be manifest in the coming decades? Second, if the well-known mismatch between formal and informal urban organization (local–state–national versus neighborhood–regional–global) is accurate, then how resistant or malleable will formal structures be in the service of informal imperatives? Third, urban life will confront the access issue of personal automobiles versus every other form of mobility. While epitomized in US settlements, this tension is rapidly becoming global in both its prevalence and its consequences.

The future of urban settlements and the lives lived therein will depend on a mix of predictable trends and human contingencies. History is the best guide to those future trends, and three are discussed here: technology, the limits to growth at urban peripheries, and the attractive power of urban centers. Caution is perhaps the best guide to discussing future contingencies, but three major issues are so apparent that they will likely confront urban decision makers in the coming generation: large versus dense settlement structures, local versus regional decision-making processes, and automobiles versus other means of mobility and access to urban resources.

Three Determinants of Urban Futures

Since the beginning of the urban era, technologies in various forms and the relative 'gravitational' pull of urban centers and rural hinterlands have been powerful determinants of urban life. These fundamental mechanisms are surely the product of human action and are never completely beyond a human capacity to intervene (Mumford, 1961). Yet, the power of such mechanisms (for example, the technology of production and the related attractiveness of center versus peripheral locations) often exerts a defining influence on urban settlements in ways that can overwhelm individual or collective action in a given time or place. Introduced below are three such large trends that may be expected to influence the future of urban life.

Waves of innovation in communications and transportation technologies occurred throughout the twentieth century. At present, these roiling changes are understood and discussed in a summary way as the emergence of an Economy (Mitchell, 1995). A new digital geography will reshape the possibilities of urban life over the next generation (Kotkin and Siegel, 2000). In particular, the Economy changes many of the incentives (e.g., economies of scale and various costs that increase with distance) that led to concentration in urban centers in the nineteenth and twentieth centuries. By weakening and sometimes inverting such incentives, the New Economy is characterized by much more footloose (or non-location-specific) production and consumption. It is now both possible and increasingly common to participate in employment, education and many other daily activities well beyond the commuting radius of a daily urban system. Under such conditions, the nineteenth and twentieth century comparative advantages of specific locations (e.g., entrepot for commodities, large physical agglomerations of workers and consumers) are being eclipsed by locational amenities such as weather and natural beauty as well as cumulative advantages that accrue to particular locations that happened to innovate first in some industry or activity.

Second, the limits of post-1945 development patterns, especially the low density suburban form prevalent in the United States for 50 years, will be tested and some expect those limits to be reached. Technological changes (with, in the United States, the full support and encouragement of several national policies) have maximized the opportunity for low-density choices and this has led to a half-century of suburbanization in urban settlements, in which the increase in built-up land area has far exceeded the increase in population or employment. The resulting development patterns have been associated with a long list of social costs, including increased traffic congestion and lengthening commutes, loss of both open space and agricultural land uses, a rise in social and ethnic segregation as well as in aggregate housing costs, and the decline of communal participation and social capital (Downs, 1995; Kunstler, 1996; Duany et al., 2000). These critiques have sought to portray as unsustainable the current low-density development regime, often labeled sprawl. Policy recommendations range from government controls on new peripheral growth to the modification of cultural and aesthetic values related to suburbanization.

Third, the attractive power of centers will wax or wane; given the diminished power and autonomy of large industrial urban centers over the preceding century, this third mechanism is likely to be closely related to changes in the first two. Paradoxically, the decentralizing trends of both the digital economy and a low-density development regime have created a powerful role for centralized command and control exploited by a select group of 'global cities' (Sassen, 1991). This centralizing function is also present on a smaller scale within regional systems, somewhat reviving a role played for smaller urban centers. In addition to this emerging economic function, urban centers may also gain a new importance derived from the limits on further growth at the urban periphery (Rusk, 1999), whether those limits are imposed by technology or by governments.

Three Issues Facing Future Urban Decision Makers

The multiple contingencies of these and other mechanisms will likely frame the important issues facing decision makers over the coming decades. Without knowing how the possibilities will turn out (a placeless city of bits or not? More growth on the undeveloped urban edge or less? A sustained re-centering of urban settlements or their permanent de-centering?), it is imprudent to list specific issues to be grappled with. But three critical issues are already apparent in the foreseeable (or more seeable) future.

First, if largeness is a consequence of a passing industrial era, then how will the more fundamentally urban quality of density be manifest in the coming decades? While the emergence of a New Economy is neither fully understood nor even universally accepted, the technological framework within which urban settlements are constructed and maintained seems to have changed profoundly. While industrialism's appetite for physical agglomeration has weakened if not collapsed, there appears to be a powerful revival of demand for density on a very large scale in a select set of global cities and on a smaller scale in centers throughout the urban system. This demand for density appears to be related less to production and distribution, unlike during the industrial era, and more toward lifestyle amenities. Breaking the link between density and largeness in the minds of urban dwellers and decision makers, which seems fundamental to the suburban reform agenda discussed above, will be a major challenge in coming decades. In many ways, of course, this leads back to the future and to a revival of Ebenezer Howard and Garden City and New Town ideas.

Second, if the well known mismatch between formal and informal organization (local–state–national versus neighborhood–regional–global, respectively) is accurate, then how resistant or malleable will formal structures be in the service of informal imperatives? Many of the changes demanded in the preceding paragraph require collective action and governmental capacity. That the ideas being debated are neither new nor complex suggests the difficulties of actually implementing a desirable future. Whether or not the public apparatus of decision–making related to urban life can be adapted to match the new and emerging scales at which urban life is being lived through new technologies and relationships is perhaps the single most important issue framed by observable trends.

Third, urban life will continue to confront the issue of automobiles versus every other form of mobility. While epitomized by US settlements, this tension is rapidly becoming global in both its prevalence and its consequences. Regardless of the scale and governance issues outlined above, physical access to some resources (perhaps a different set than those of today) will continue to be a fundamental rationale for urban settlements. The access problem is solved through mobility of some form. The worldwide trend toward individual automobile mobility (whether that trend moves from the large base of car use in the United States or the smaller but rapidly growing base found in the developing world) will likely join if not eclipse other specific critical priorities facing urban decision makers. Ironically, the negative environmental impact of increasing automobile use is as global an urban issue as the positive relationships of the New Economy. The intersection of combustion engines, urban settlement patterns, and cross-national environmental degradation will challenge urban life in powerful and perhaps decisive ways.

Urban Megaprojects

Abstract

In the context of the intercity competition favored by urban entrepreneurialism, urban megaprojects play a significant role not only for their ability to attract investment and generate high returns, but also as iconic symbols of the new economy. In addition to their scale, they are characterized by the mixed nature of their components and land uses, the use of various forms of public–private partnership and their preferred location in areas of former residual use. Their expansion to a large number of cities around the world has increased their diversity and with it the need to expand comparative analytical studies.

Introduction

A historical reading of urban processes can identify over time the development of large urban projects of various types in any of the world's most significant cities. However, when the term megaproject is used in contemporary urban studies it does not refer generically to these developments, but rather to specific types of intervention in the urban space.

According to Altshuler and Luberoff (2003), during the 1950s and 1960s there was a strong flow of investment in American cities. A highly significant part of these investments went into promoting megaprojects, largely linked to new transport infrastructures, e.g., freeways and airports, but also aimed at urban renewal. Just as occurred in much of Western Europe, these investments must be linked to the development of postwar Fordist state (Diaz Orueta and Fainstein, 2008).

Europe also had to rebuild its war-torn cities. In fact, in European cities the emphasis was on the construction of housing, both in districts destroyed by war and in previously nonurbanized areas on the urban periphery (Fainstein, 2008). By contrast, interventions in the USA primarily focused on inhabited areas, in many cases involving the demolition of slums. While public provision of housing generally played a crucial role in Europe, the United States relied primarily on the private sector and nonprofit organizations to invest in sites freed up by slum clearance.

Megaprojects played an important role in shaping a new urban environment characterized, among other features, by proliferating highways used by growing numbers of people, who progressively agreed to the use of private vehicles and the construction of large buildings, which were said to ensure a more efficient functioning of the city, while improving housing shortages and facilitating the attraction of capital (Diaz Orueta and Fainstein, 2008).

Since the late 1960s and very clearly in the 1970s, such developments began to meet problems, for several reasons. One was growing opposition by movements to protect the environment and national heritage (Altshuler and Luberoff, 2003). A significant proportion of new buildings erected on cleared land represented a break with the collective memory of the city. In addition, various working class movements also put up strong arguments based on the social consequences of many megaprojects, which often involved the displacement of hundreds of thousands of people, especially in the USA, with the consequent destruction of communities, and also exposing the way potential benefits were unevenly distributed socially. As Salet (2008) suggests, from the late 1960s progrowth coalitions were faced with the debate about social polarization, articulated around issues, such as social inequality, racism, education, and unemployment. Already in the 1970s, and especially following the oil crisis, environmental concerns were also forcefully entering urban agendas. On the other hand, increasing fiscal constraints and decentralization policies on the part of the state acted as additional constraints (Diaz Orueta and Fainstein, 2008). It is clear that by the mid-1970s developers had already entered what some writers have termed the 'do no harm' phase, as projects were transformed to avoid emerging resistance (Altshuler and Luberoff, 2003).

Within a few years a new generation of urban megaprojects began to appear. From the late 1970s thinking centered on the idea that the fundamental problem cities had to face was economic crisis and decline. There emerged what some authors have called the new urban policy, aimed at ensuring economic growth of cities, promoting competitiveness and implementing new forms of local government to respond to the demands of economic globalization (Swyngedouw et al., 2004). By the early 1990s, these trends had become consolidated, giving rise to a new generation of urban megaprojects, the evolution of which has been inescapably linked to the neoliberal urban restructuring experienced by North American and European cities (Brenner and Theodore, 2002). Megaprojects came used as a way to reposition cities in the global economy (Lehrer and Laidley, 2008).

A New Generation of Urban Megaprojects

In this new era, development of megaprojects constituted a central tool in strategies of political and economic elites to improve urban competitiveness (Del Cerro, 2013). As Fainstein (2008) argues in her analysis of New York, London, and Amsterdam, these actions have been shown to be extremely useful in attracting international investment of many kinds. In these three cities, as in others, there was a major transformation of their economic bases, leaving behind industrial specialization to focus increasingly on offices, leisure, and tourism, while markedly increasing new spaces for luxury homes. A significant number of the urban megaprojects have been developed in old abandoned industrial areas that have been completely

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74052-9

transformed, giving way to new spaces that symbolically represent the progress of the new economy. Furthermore, although the megaprojects are placed in specific locations, their analysis requires consideration of different territorial scales. Urban megaprojects are important for lobbying and decision-making networks at interregional, transnational, and international levels. Therefore, the analysis of local policy making must be carried out from a multilevel perspective (Salet, 2008).

New megaprojects have not led to the demise of other developments focused on building large transport related infrastructures, the energy sector or supply of basic necessities, such as water (Diaz Orueta and Fainstein, 2008). In fact, the analysis of these types of megaprojects remains a very noteworthy subject of attention, especially with regard to major transport infrastructure (Flyvbjerg et al., 2003; Priemus and van Wee, 2013).

However, contemporary urban research focuses primarily on other types of megaprojects. These are large developments that feature different content: mixed residential use, tertiary spaces, utilities of various kinds, new transport infrastructure, etc. Megaprojects thus affect large surface areas where a change in land use and new construction or total rehabilitation of old buildings occurs. Their symbolic spatial component is crucial; hence the centrality given to the designers of these spaces, converted into real superstar architects who stamp their distinctive signatures on iconic reference points of contemporary cities.

Moreover, the scale of the projects poses a growing challenge to traditional financial instruments and urban management (Lungo, 2002). Directly linked to the change of scale, one of the clearest peculiarities of new megaprojects as already indicated is their mixed character. For example, when analyzing the waterfront development in the city of Toronto, Lehrer and Laidley (2008) emphasize the mixed use including housing, different types regarding tenure and size, built with spaces for offices and small trade, and surrounded by parking areas, repositories, and natural amenities.

To finish this outline of an introductory approach to the new generation of urban megaprojects, it is necessary to add a third dimension to complete the above references to its mixed character and scale. This is the location: what urban spaces are chosen to situate the megaprojects? In general, the preferred location is in old industrial areas, ports in decline or other terrains with a residual urban use, usually but not necessarily outside the city center. It is common that these spaces are not well integrated with the rest of the city, reinforcing the tendency toward specialization and spatial monofunctionalization (Salet, 2008). In the US and European cities, these major projects, characterized by repetitive architectural designs that contribute to the commodification of the city, are generally located in areas devoid of interaction between old and new spaces, large and small, which gives centers its special and distinctive character (Fainstein, 2008) (**Figure 1**).

On the other hand, it is often noted that in contrast to what happened with the old megaprojects, location on urban fringes has reduced social conflicts, as the population it less likely to be directly affected by their construction. However, this latter view must be qualified since the increasingly abundant literature on urban megaprojects shows several case studies in moderately developed countries in which the choice of location has impacted directly and negatively on important population groups. This is the case in Buenos Aires, where the development of Puerto Madero megaproject, on the waterfront, threatens the survival of the Villa 31, a shantytown inhabited by more than 20 000 people and located alongside some of the most sought after neighborhoods in the city. Another example is the attempt to build a new airport for Mexico City, the location of which would impact directly on the lives of the communities in that

Figure 1 Buenos Aires: Puerto Madero Waterfront. Photo by Fernando Diaz Orueta.

area. In fact, this megaproject led to a social conflict of huge proportions that eventually brought about its closure in 2002 (Flores Dewey and Davis, 2013). In another context, Beijing's hosting of the Olympic Games and the major urban developments it deriving therefrom generated the transformation of large areas of the city causing, e.g., the gentrification of different historic neighborhoods (Ren, 2009).

Urban Entrepreneurialism and Megaprojects

Already in the late 1980s, some authors were calling attention to the transition from a model of urban governance based on managerialism to another based on entrepreneurialism (Harvey, 1989). In this new model, urban policies favor competition among cities, in the hope that economic growth will generate prosperity, welfare, and employment for the majority of the population. Although initially developed in the United States, urban entrepreneurialism also reached the cities of Western Europe. Urban megaprojects are a strategic element of urban entrepreneurialism, transmitting an image of status and power and thus attracting investment (Dyble, 2013). Therefore, they are primarily oriented toward the market, competitiveness and profit, leaving social commitments, such as employment and affordable housing in the background. Ultimately, it comes down to getting significant returns, and that is basically achieved through the construction of luxury residences and hotels, large-footprint office towers, and shopping malls (Fainstein, 2008).

Compared to other developments, the process of definition, approval, and implementation of urban megaprojects makes their management enormously complex. In fact, a large part of the literature on these behemoths analyzes not only the emergence of new forms of management and planning, but also funding and taxation mechanisms. All this is in a context of growing multilevel interrelationships in which the number and diversity of those involved in the decision-making process multiplies. Given the complexity of these projects, their implementation spreads over time, subject to the vagaries of economic cycles. Therefore, study of the coalitions supporting megaprojects and their multilevel relationships is essential in order to understand not only their gestation and administration, but also their sustainability over time and even, when it does occur, their failure.

Such coalitions work hard to obtain social support in favor of the development of megaprojects. This support is achieved through institutional and politicoeconomic structures that redirect public attention away from controversy and, therefore, generate or at least try to generate the depoliticization of megaprojects (Lehrer and Laidley, 2008). For example, in the case of the waterfront development in Toronto, a city studied by these authors, public participation was not initiated at the time of considering new development choices, but only once the decision as to which option was preferable had been taken. In fact, the majority of megaprojects erected in many cities of the world have not had any participative processes, either before or after approval.

Such has been the case with most of the megaprojects in Latin American cities. In fact, in these cities it is common, once the decision to go ahead with such a project has been made, for a process to operate that openly bypasses both the urban planning offices of and even political channels, regarded as overly reliant on democratic public debate (Lungo, 2002). As a result, these projects serve the interests of a small minority while producing displacement of the less advantaged from their neighborhoods, further deepening the processes of urban segregation and social exclusion. This tends to reinforce the existence of islands of modernity surrounded by large areas of poverty.

Promoters of megaprojects linked to major transport infrastructure are also perceived to evade and even violate the practices of good governance, transparency, and participation in decision-making processes (Flyvbjerg et al., 2003). Such practices are perceived as hindrances hampering development of the projects. This approach can produce profound and lasting environmental damage, given that by not taking into account the need for impact assessments or doing them in a very lax way, infrastructures that should never have been erected or built without the necessary precautions are constructed.

In addition, this markedly business-friendly orientation exerts substantial pressure on local governments, especially in a climate of severe financial constraint. For example, Dyble (2013), analyzing the case of Skyway in Los Angeles, highlights the way its management evolved so that, in the context of globalization, the emphasis on a transport policy that prioritizes long-distance connections rather than local or regional integration led to this major infrastructure becoming an important part of urban governance now run largely according to financial criteria. In fact, given public finance constraints, governments have been more inclined to negotiate the entry of private funding. But there is no doubt that the growing presence of private funding means that the public sector loses an important part of the ability to control projects.

Since the contexts where megaprojects arise are varied, both socioeconomically and from the political and cultural perspectives, it is possible to detect significant differences and peculiarities between different experiences. In this regard, comparative studies are very revealing. For example, Doucet (2013) discusses two projects, one local initiative in the city of Rotterdam and one in Glasgow, promoted by the private sector. Comparative analysis identifies important differences between European cities, highlighting the way that when municipal authorities lead and coordinate the project, business objectives are more easily achieved than when the public sector is limited to facilitating the activities of private developers. Doucet, without abandoning the perspective of urban entrepreneurialism, also stresses the need to analyze the role of individual actors and leaders involved in the process.

In an equally comparative key, Fainstein (2008), analyzing different megaprojects in the cities of New York, London, and Amsterdam, highlights how in the latter two cities, and particularly in Amsterdam, a true social democratic ethos had survived. This means that, in contrast to what happened in New York, the two European cities at least until 2008 held developers to certain social and environmental requirements. Above all, even with difficulties the welfare state seems to present greater resistance in countries like the Netherlands, which would imply a model of urban governance with greater government leadership and a certain level of commitment to

egalitarian goals. In London, recent research shows how some of the large urban operations associated with hosting the 2012 Olympics have generated powerful gentrification processes (Watt, 2013). In other European cities, such as Barcelona, the urban model is increasingly oriented toward competitiveness, displacing other considerations to the background (Degen and Garcia, 2012).

In the coming years, with the consolidation of the neoliberal vision of the European Union, it is foreseeable that the reality will increasingly resemble that of the USA, with a clear deepening of social inequality, a simultaneous increase in poverty indicators and the concentration of wealth in the hands of very small sectors of the population.

Public–Private Partnership

Although the relationship between the public and private sectors is far from new in the history of urban development, it has become more intense with the expansion of urban entrepreneurialism adopting new and varied forms of collaboration. This is understood as essential for competition between cities and has reached such extremes that it is sometimes not easy to distinguish the specific role played by the public and private sectors and the meaning of the performance of each. Therefore, results of the collaboration between both sectors vary from case to case, although insofar as there is a very strong tendency to prioritize economic benefits, the extent of their commitment to egalitarian goals is generally very limited.

Cooperation between the public and private sectors has resulted in the creation, in numerous cities and under various formulations, of institutionalized collaborative spaces. For example, in 1991 Bilbao created the Bilbao Metropoli-30 association, formed by different public and private entities, which was instrumental in establishing the new image of a city trying to overcome a deindustrialization crisis by projecting an innovative character (Rodriguez and Martinez, 2003). A year later, the creation of the public company Bilbao Ria 2000 brought it well within the governance by business interests. This new company was responsible for coordinating projects and developments subsequently implemented in the fields of urban planning, transport and the environment, including the Guggenheim Museum in the Abandoibarra district, the flagship project in reshaping Bilbao (Gonzalez, 2003; Vicario and Martinez Monje, 2003) (**Figure 2**).

Analysis of these entities helps identify the composition of the coalitions that promote megaprojects and the specific weight and capacity for determination of urban agendas of each of their different public and private members. While in some cities leadership can be held by local public authorities trying to control and direct growth, in others it is business sectors that set priorities and determine ways forward. This happened, for example, in most Spanish cities during the economic boom before the outbreak of the crisis in 2007/2008, when corporate power and political will completely overlapped to favor the growth of a massive speculative bubble that was reinforced inter alia, by the development of a number of megaprojects of diverse nature, new museums and cultural centers, major housing estates with tens of thousands of new homes, oversized airports, theme parks, large office complexes, industrial parks, shopping malls, etc.

To understand the real scope of the public–private partnership in the development of megaprojects, consideration of the socioeconomic and political context is crucial. For example, in many countries these large urban operations have coincided in time with profound economic and political changes that have greatly affected the role of the state. Specifically in Latin

Figure 2 Bilbao: Guggenheim Museum. Photo by Fernando Diaz Orueta.

American cities, in the 1990s as a result of decentralization and privatization, there was a redistribution of regulatory powers between different levels of government (local, regional, national), as well as the roles played by private institutions and local community organizations (Lungo, 2002). This led to the emergence of new urban management structures reflecting the confluence, sometimes not without conflict, of the public and private sectors, and the current multilevel nature of urban processes.

Some writers believe that, given the complexity in terms of networks of entities involved, the heterogeneous and not infrequently divergent variety of interests and contradictions inherent in megaprojects, it is to be highly recommended that management should be led by the public sector and, in particular, by local governments. Lungo (2002), taking as reference the Latin American urban reality but reaching conclusions that can be extrapolated to other territories, states that municipalities are better able to ensure that other levels of government in a reduction of the negative external factors of megaprojects, ensuring the involvement of locals and weaker members and promoting a more balanced distribution of benefits.

Public–Private Partnership and Urban Planning

The relationship between urban megaprojects and urban planning processes is a relevant concern. In many cities, the development of these projects collides with the procedures and regulations characteristic of the traditional tools of urban planning. In fact, new ideas have been boosted since the 1980s, such as strategic planning, one of the main objectives of which has been to expedite the implementation of these major developments, favoring public–private partnership (PPP) strategies. Also, as Salet (2008) recalled, it should not be forgotten that today urban planning is not a question of urban or regional planners or even local coalitions, but that an approach based on interconnectivity in the network society.

Also with reference to planning it is necessary to stress the need to differentiate urban realities, given that the meaning of planning in different cities is very distinct. For example, when Bezmez (2008) analyzes Istanbul she points out that, unlike most European or American cities, in that city planning has never been instrumental in the development of megaprojects. Conversely, Fainstein (2008) in her comparative analysis of New York, London, and Amsterdam highlights the importance of the planning process in these three cases, as well as the peculiarities she found. So while in London and New York megaprojects are part of a more comprehensive planning process than seen in earlier times, in Amsterdam, a city where overall planning has historically dominated, a rethinking of spatial strategies beyond a polycentric model can be observed. In contrast to the above, and referring to the city of Manila, Shatkin (2008) points out the need to carry out a proper analysis that goes beyond the idea that globalization implies an inexorable process of 'Westernization'. Thus, in relation to the planning and development of megaprojects, Shatkin concludes that Manila is undergoing a massive privatization of urban and regional planning. That means that the major developers have become responsible for urban development planning, assisted by government authorities.

Results of Megaprojects

Many of the scientific studies that examine the new generation of urban megaprojects maintain a critical perspective on their results. The supposedly favorable effects on urban economies and regional development are difficult to measure in quantitative terms and, on the contrary, there are many indicators that point to significant negative impacts from the social and environmental point of view. However, as already pointed out above, this does not mean that the promoters of megaprojects have not made a notable effort to present them publicly as key tools in moving toward a social and environmentally balanced model city. The image projected of megaprojects through urban marketing refers to a sustainable and equitable city where new and compelling urban attractions appeal to visitors and new residents interested in leisure and culture. As such, a city in which economic growth would support citizen participation, deepening democracy, social equality, and respect and even environmental recovery.

However, analytical studies of megaprojects portray a very different panorama. These studies mostly reflect the growing power of some economic and political elites that border the democratic mechanisms of decision making to boost urban entrepreneurialism. As a result, in the last two decades megaprojects have been one of the elements that have contributed to increased urban segregation and particularly gentrification.

Another aspect often queried in relation to megaprojects is that of additional costs. The already high planned budgets are almost systematically exceeded. In fact, it is common to establish demand forecasts well above actual expectations, underestimate the environmental impact and exaggerate the expected economic benefits of the megaproject. Ultimately, the low estimate of costs does not appear to be due so much to inadvertent error as to deliberate deception (Flyvbjerg et al., 2003). Thus, both in terms of cost overruns and treatment of financial risks, similar trends are detected in different types of megaprojects, including major transport infrastructures (Altshuler and Luberoff, 2003). These writers suggest the need to improve accountability measures in order to detect and resolve the systematic underestimation of costs. This is not a trivial matter, since in some cities the problems created are extremely burdensome. For example, dragging the huge debt the city of Madrid (7500 million Euros at year-end 2012) is explained in part by the significant overspending that occurred on a megaproject that was in itself enormously costly: the burial of the M30 urban motorway ring. But although the most extreme, this is not the only case of a Spanish city in which the development of one or more urban megaprojects, coupled with the usual extras, has helped lead to choke the public purse. The same thing happened with, e.g., Valencia's City of Arts and Sciences or in Zaragoza's large urban projects boosted by the International Water Expo 2008 (**Figure 3**).

Yet despite this negative balance, the use of megaprojects as instruments for construction and transformation of cities has become increasingly common, leading to what other writers have called the paradox of megaproject development (Flyvbjerg et al., 2003; Altshuler and Luberoff, 2003; Del Cerro, 2013).

Weak social opposition, partly explained by the efforts made to try to present megaprojects as virtuous developments that should therefore fall outside the scope of urban disputes,

Figure 3 Valencia: City of Arts and Sciences. Photo by Fernando Diaz Orueta.

have facilitated this apparent paradox. As already noted, in most cities in the developed world the number and intensity of social movements has been less than at previous historical moments. The strength of legitimizing discourse and sophisticated marketing strategies, together with the mixed nature of the uses of megaprojects and their peripheral location, have contributed to the maintenance of consensus, or at least of social disinterest. In these countries, the weakness of social resistance to the new generation of megaprojects, although these have sometimes occurred (Diaz Orueta, 2007), contrasts with the strength of the protests that arose over previous megaprojects (Lehrer and Laidley, 2008). But in any case, when the perspective is extended to cover the cities of the global South and other countries of intermediate development, the situation changes dramatically with important and sometimes successful social mobilizations taking place (Flores Dewey and Davis, 2013).

Problems and Methodological Challenges in the Study of Urban Megaprojects

As mentioned above, in the last 10 years there has been a sharp increase in research focused on the new generation of urban megaprojects. The remarkable growth in the number of case studies has been accompanied by an increasingly intense effort to achieve generalizable results, especially by conducting research of a comparative nature involving very different cities. However, today there are still a number of important features for which only partial answers are so far available and that, therefore, continue to pose challenges for research on aspects of urban megaprojects.

First of all, it is necessary to go further in establishing the differences and similarities between the different experiences, developing a comprehensive and systematic comparative analysis. To begin with, the comparison of urban megaprojects in the cities and countries of the global North should be extended. But besides this perspective at least two other types of investigation are required: those that compare the experience of the global North to that of the global South and those focusing exclusively on cities of the global South. In this regard, it is important not to turn the conclusions of research conducted in countries of the global North into general categories, extrapolatable to other urban areas. Of course, this does not mean that there are not more or less intense connections between some cities. For example, the experience of urban transformation undergone by Barcelona with the hosting of the 1992 Olympic Games had a major influence on the development of urban megaprojects in several Latin American cities (Lungo, 2002). However, this in no way meant slavish imitation of what happened in Barcelona. The political, economic, and social contexts, and the role played by urban planning and the public sector, are so diverse, that results necessarily differ profoundly.

In that sense, one of the main problems faced by these studies is the difficulty, even higher than in other types of research, of standardizing information to enable rigorous comparisons. This question arises not only in regard to the construction of comparable quantitative indicators, but also the great diversity in regulatory frameworks, planning traditions, functioning of political systems, economic context, etc.

A second aspect, partially addressed to date and in need of more thorough and systematic consideration, is the impact produced by megaprojects on urban social structures. According to research to date, most of these megaprojects primarily reflect the specific interests of certain political and economic elites and thus favor the development expected by these groups to the detriment of others. Therefore, as suggested by, e.g., Lehrer and Laidley (2008), it is necessary to undertake a class-based analysis aimed at understanding to what extent and how

the proliferation of megaprojects could be influencing the evolution of social inequality in cities.

Third, research to date has interpreted urban megaprojects as a given factor of the new urban reality. A characteristic of contemporary cities that can be analyzed, sometimes very critically, but for which no alternatives are discussed (Diaz Orueta and Fainstein, 2008). However, with the level of maturity that has been reached by now, megaproject research should urgently address this issue. Consequently, it is necessary to question their inevitability, consider whether it is worth keeping these megaprojects and, if so, under what conditions and for what purposes.

A fourth aspect, indubitably linked to the foregoing, is that the global economic crisis and the interpretation thereof should occupy a central place on the agenda of megaproject research. The crisis affects the whole planet, albeit unevenly, and its implications are clearly visible in the cities. This crisis has called into question the bases of the justification of urban policies of the past two decades, including urban megaprojects. In any case, given the complexity of the moment, it is premature to be sure that neoliberalism will soon be outdated.

There can be no doubt that the global crisis affects in an especially intense way some essential conditions that have allowed the development of megaprojects. Thus, for example, the difficulties of the private sector to access credit have increased, the public sector faces a situation of deep cuts and severe indebtedness and, on the other hand, the demand for new office space, housing, etc. has decreased markedly, even disappearing in some countries (Diaz Orueta and Fainstein, 2008). Furthermore, given the lengthy time required for their development, some have been paralyzed, at least temporarily, while others remain although undergoing major reformulation.

It should also be remembered that the crisis does not affect all cities with the same intensity. Consider, for example, the scenario of growth in China compared to the structural decline since 2008 has been driven economy of the countries of Southern Europe. Furthermore, while some cities are raised through the crisis trying to shape a different model, others rely on returning in a few years previous to the path of growth. In the latter case, it is not intended to change the model so as to take a series of measures to promote economic recovery. It is in this last key that should be understood otherwise incomprehensible bets, such as how, for example, that by the leisure resort Eurovegas would occupy an area of over 750 ha on the periphery of metropolitan Madrid that, if it goes ahead, would become one of the largest facilities of this type in the world. This action is not only hard to justify from the social and environmental point of view, but also in economic terms taking into account the situation of suffocation and bankruptcy that territory is currently undergoing.

A further consequence of the global crisis is a revival of citizens' rejection of megaprojects. In a context of strong social cuts, with a sharp increase in poverty, unemployment, and the number of homeless people, it is not feasible to maintain previous levels of consensus about megaprojects. The conditions that, for a long time, helped many cities to place them outside the realm of public debate have disappeared and now, on the contrary, the demand for accountability for the disastrous management of some of the megaprojects developed in previous years continues to grow. Possibly more than a few western countries have now entered a phase of social mobilization focused on urban issues, in which the debate on megaprojects occupies an important place.

Briefly, the challenges to be faced by urban research on megaprojects in years to come are varied and complex. However, the growth of studies in this field of research, the diversity of approaches and the wide geographical coverage achieved, guarantee an excellent position from which to continue to deepen our knowledge.

Urban Neoliberalism

Ugo Rossi and Alberto Vanolo, Università di Torino, Turin, Italy

Abstract

The rise of neoliberalism as the hegemonic art of governing contemporary capitalist cities traces its origins back to the 1980s, being associated with the ascent of conservative governments in the Unites States and the United Kingdom pursuing economic development strategies based on the conventional free market ideas. Since then, urban neoliberalism has spread across the globalizing world through an increasing emphasis being laid on the entrepreneurialization of local government, the privatization of public services, and the commodification of urban space. In this context, urban neoliberalism has taken the form of a highly mobile government technology, giving rise to a tremendous variety of politico-economic regimes across the globe through processes of hybridization and variegation. This article describes the variegated geographies of neoliberalism, ending with an analysis of the recent global recession which is understood as a crisis of (urban) neoliberalism.

Introduction: The Neoliberal Art of Governing Cities

Over the last two decades, the notion of neoliberalism has become key to contemporary debates and empirical inquiries within the social sciences concerned with the investigation of urban and regional development processes. Since the late 1970s onward, the economic policy that subsequently came to be known as neoliberalism supported the development of allegedly free (or 'anarchical': Jessop, 2002) market relations led by an ideology of competitive individualism, combined with policies aimed at socializing the costs of deficits in the private sector through generous capital injections to firms and banks during recessions. The success of neoliberal policies, being dogmatically imposed in the post-cold war era as the only viable option (a 'new religion': Peet, 2003) after the decline of the Keynesian mode of regulation, has been concomitant with the globalization of the international economy, impinging upon economic development processes at a variety of geographical scales, including the urban and regional levels.

Prior to the rise of neoliberalism, there is the end of an era of intense and apparently unlimited economic growth commonly recognized as the 'golden age of capitalism' (Marglin and Schor, 1991), beginning after the World War II and ending with the economic and geopolitical turbulences of the 1970s. In the United States, the 1980s witnessed the embrace of the so-called Reaganomics, the supply-side economic policy pursued by the Federal Administration during Reagan's presidency. According to the supply-side approach, in order to revitalize markets and attain higher rates of economic growth, it is necessary to reduce the fiscal pressure on businesses and capital holders so as to stimulate private savings and investments. The conservative and entrepreneurialist turn changed in depth the way in which economies and societies were governed in the United States as well as in the United Kingdom, which at the time was undergoing a parallel neoliberal '(counter)revolution' led by the Prime Minister Margaret Thatcher: from the privatization of state corporations to the controversial Poll Tax, which introduced a fixed tax per adult resident, leading to protests all over the country and in the city of London most intensely. While the controversy that developed around the so-called 'Poll Tax in Britain' presaged the end of Margaret Thatcher's premiership, as the 'iron lady' resigned few months after the approval of the tax, in the United States the adoption in 1978 of the Proposition 13 in the State of California – a constitutional amendment deliberating that the maximum amount of taxation on real property should not exceed the 1% of the property value – paved the way for Ronald Reagan's ascent from the governorship of California to the Federal Presidency. Indeed, the adoption of the amendment inspired an antifiscal campaign known as 'taxpayers' revolt' throughout the country, which prepared the ground for Ronald Reagan's successful presidential election in 1980.

The neoliberal (counter)revolution of the Reagan–Thatcher era had strong repercussions at the urban scale, opening the way for an unprecedented deregulation of housing markets and generally for an irreversible shift to the entrepreneurialization of local government and the privatization and commodification of urban public space (Smith, 1996; Mitchell, 1997; MacLeod, 2002). The translation of the neoliberal ideology into an instrumental and geographically mobile 'intellectual technology' relied on a globalizing system of policy exchanges and transfers, mobilizing a variety of institutional intermediaries and local importers of 'ideas from elsewhere' (Ong, 2007; Prince, 2012). In the Unites States, in order to build the reputation of neoliberalism as the emerging conventional wisdom within the wider public, politico-economic elites have drawn on the contribution of existing or newly established consultancy agencies funded by public and private donors (Peck, 2010). The neoliberal 'revolution' has thus changed the way in which at one and the same time the economic base and the politico-institutional realm of cities are conceived and concretely organized. As 'post-cold war' neoliberalism can be generally understood in a Foucauldian sense as the 'art of government' regulating and dictating the expansion of the economic form of capitalism into the social sphere (Lemke, 2001), through processes of individualization and entrepreneurialization of the self (Burchell, 1993; Lazzarato, 2009), urban neoliberalism more specifically is to be viewed as the translation of the logic of free market capitalism into the urban domain of sociospatial relations. As the next section of this article shows, in the late 1980s, David Harvey was the first social scientist to clearly

 http://dx.doi.org/10.1016/B978-0-08-097086-8.74020-7

identify the rise of a neoliberal art of governing cities, through his conceptualization of the entrepreneuralization of urban governance in US cities over the 1980s, even though at that time he did not explicitly use the term neoliberalism. Harvey's understanding of urban governance in incipient neoliberal times serves as a point of departure here, preparing the ground for the following two sections of this article which are devoted to the analysis of the geographical expansion of urban neoliberalism over the last three decades. Finally, the concluding section focuses on the supposed crisis of urban neoliberalism as a consequence of the ongoing global recession, whose urban roots are customarily associated with the 'credit crunch' of 2007–08 that affected real estate markets in the US economy and elsewhere.

The Entrepreneurialization of Urban Governance

In a path-breaking article, David Harvey (1989) accurately illustrated the causes and the effects of the process of change in the sphere of local government, which he analyzed in terms of a shift from the public-managerial approach prevailing until the urban crisis of the 1970s to the entrepreneurialization of urban governance associated with the advent of a pro-growth mode of regulation. In his article, Harvey distinguished between the 'government' and the 'governance' of cities and regions, anticipating a conceptualization that became widely accepted within the field of urban studies and the wider social sciences in the following years. In his account, the former (government) identifies a hierarchical and 'managerial' governing style, founded on the primacy of the public sector and aimed at redistributing city revenues through the provision of services to firms and households. On the other hand, the latter (governance) highlights the decentralization of governing procedures in a context of public sector's reduced institutional capacity and of rising importance of public–private partnerships and related processes of negotiated decision making.

To urban and regional scholars, further expanding the conceptual framework elaborated by Harvey, entrepreneurial cities appeared to be crucial sites where politico-economic elites are in a position to experiment with innovative capital accumulation strategies, tending toward the immaterialization of the economic process (Hall and Hubbard, 1998). While Harvey verified these dynamics in light of the case study of Baltimore and its regenerating waterfront, related processes of socio-spatial restructuring were observed in a number of cities in the West and elsewhere. In Britain, the deindustrializing cities in the North of England (Newcastle upon Tyne, Leeds, Manchester, Liverpool) dealt with policies and plans of urban regeneration aimed at stimulating private businesses, especially small- and medium-sized enterprises, and at revitalizing inner-city areas which were affected by economic and demographic decline (Ward, 1997). Related dynamics of urban regeneration and changing economic governance were also noticed in other large cities and smaller towns in North America and Western Europe (Judd and Parkinson, 1990) and subsequently in Asia, as it is discussed below in this article (Jessop and Sum, 2000; Wu, 2002).

Since the 1990s, the discursive and material forces of globalization exerted a growing influence on the evolution of urban entrepreneurialism and the trajectories of economic development and socio-spatial restructuring. As Harvey had explained, politico-economic elites across the world were urged to connect cities and regional spaces to economic, political, and cultural relations of global reach. The growing interplay of global and local spatialities shapes in depth urban governance processes, which are driven by the so-called 'local politics of globalization' (Swyngedouw, 1992; Cochrane et al., 1996). The 'new urban politics' becomes thereby a crucial terrain of investigation with reference primarily to Anglo-American cities and metropolitan areas but also to cities in other contexts of advanced and emerging capitalism.

Variegated Geographies of Urban Neoliberalization

As Aiwha Ong (2007) has pointed out, the neoliberal regime of institutional governance and capitalist accumulation should be viewed as a mobile governmental technology, constantly traveling through a variety of geographical contexts and related sociopolitical cultures. For instance, the Chinese experience, with its unique combination of authoritarian state and unregulated market, reads as an example diverging from the Anglo-American ideal type of neoliberalism (He and Wu, 2009). By approaching neoliberalism as a political-economic practice, it will be evident that the neoliberal mode of regulation relies on existing sociocultural institutions, producing a wide range of hybrid formations (Brenner et al., 2010).

At the same time, the hybridization of political and institutional forms should not lead to believe that the transition to urban neoliberalism is linear and consistent with local values and sociocultural diversities. In the vast majority of cities in the South of the world, the effects of neoliberal policies have been pervasive, eradicating existing cultural, economic, and sociopolitical institutions. In the 1980s and the early 1990s, the Washington-based financial institutions (essentially the International Monetary Fund and the World Bank) recommended a set of economic and social policies (the so-called 'Structural Adjustment Programs'), which were approved and implemented without concerting decisions with the local citizens, with strong repercussions on the most deprived urban areas (Peet, 2003). Adjustment programs were forcefully adopted by those countries receiving financial aid and rescheduling debt payments (on the basis of the so-called 'conditionality principle'). These plans were deeply informed by neoliberalism as an ideology and policy rhetoric, under the banner of the so-called 'Washington Consensus Decalogue', which prescribed allegedly universal recipes for the recovery of national and urban–regional economies (Escobar, 1995; Power, 2003).

Macroeconomic and sector-specific policies, mainly elaborated at the national level, have had deep implications for cities in the South of the world. The joint effect induced by the privatization of important public services, the closure of a number of state-owned corporations, and the bankruptcy of manufacturing industries that previously benefited from public subsidies, has had serious consequences on local societies, leading to rising unemployment rates and generating novel forms of exclusion from the labor market (Riddel, 1997). These processes have also led to the expansion of the informal

underground economy. Job losses, the shrinkage of the state sector, and the fall in living standards have forced the city dwellers to rely on a variety of sources of experimentation and commonality; shared relational capital, unused land converted into community gardens, informal trading and street vending are customary responses to poverty and deprivation in the cities of the Global South (Simone, 2004).

In this context, existing welfare states have been restructured and widely dismantled: educational and health care services have been drastically reduced, the already scarce supply of public housing has been halved on average, the price of imported food has considerably increased as a consequence of the devaluation of local currencies, while large portions of fertile land have been reconverted to export-oriented productions (Harvey, 2005). These processes of socioeconomic restructuring have led to the expansion not just of the informal economy but also of the illegal, criminal economies: newly formed street gangs and urban mafias have proliferated, engaging in large-scale organized theft and drug trade through increasingly transnational networks (Wacquant, 2008). In a context of increased poverty and hardship, large cities in the South indeed tend to become less safe places to live in. In the face of perceived or actual threats, the so-called 'transnational capitalists' (Sklair, 2002), that is those involved in the most profitable sectors of the economy, such as the oil industry for instance, respond to this situation by tightening security systems and militarizing their residential spaces in a context of neoliberalization of violence where exceptional violence is transformed into exemplary violence regulating the relationship with 'the other' (Springer, 2012). In general, social disadvantage has intensified in large cities and metropolitan areas, particularly affecting migrants and the ethnic minorities. The ambivalent effects of neoliberal urbanism are highly visible in the most dynamic city regions (such as the industrial coastal cities of South China, the fast-developing cities in the Middle East such as Dubai, the most famous as well as established global cities in the West like London and Los Angeles), where migrants are employed on casual bases in the industrial and the service sectors under conditions of unbearable workloads, low wages, uncertain contractual status, and precarious housing (Buckley, 2012).

The transnational governance of development processes in the South have also evolved over the time. The normative and straightforward approach to economic restructuring characterizing the Structural Adjustment Programs in the 1980s has become softer in many respects. The basic logic underlying development programs, however, appears to be immutable. For instance, despite the asserted good intentions, the financial aids provided in order to attain the Millennium Development Goals (MDGs) identified by the United Nations (from poverty alleviation to the reduction of infantile mortality rates, from the pursuit of an environmentalist agenda to the promotion of interstate and supranational agreements for international development) are persistently subject to IMF conditionality, which dictates the transition toward modes of social and economic organization and development based on the neoliberal agenda (Amin, 2006). At the same time, recent development programs like the MDGs are sustained by increasingly more sophisticated governmental apparatuses mobilizing calculative practices of information profiling and knowledge exchange, aimed at enhancing the neoliberal values of responsibilization and entrepreneurialization of the poor in the Global South (Ilcan and Phillips, 2010).

Whereas economic development policies adopted in poorer and emerging countries in the South have gradually abandoned the shocking therapies of first-generation neoliberalism, the 'original' forms of neoliberalism (those elaborated and commonly practised in the West) have changed over the years, and they will certainly change in the future, without losing their distinguishing features, relating to the emphasis laid on goals of economic growth to the detriment of those of social justice and wealth redistribution. After the rise and the triumph of ultra-liberal approaches during the Reaganian–Thatcherian decade, the 1990s and the first half of the 2000s have seen the reformulation and the reframing on novel discursive bases of neoliberalism as a politico-economic discourse and as a policy practice. In the attempt to conceptualize the recent evolution of neoliberalism, geographers Jamie Peck and Adam Tickell (2002) have provided an influential interpretation of the shift from an unconditionally deregulatory policy rationale, defined as 'roll-back neoliberalism,' which characterized the Reagan–Thatcher era, aiming to extinguish the social-democratic legacies created by the Keynesian regulation of capitalism, to a renewed neoliberal approach, more positive and 'constructive,' aimed at rebuilding the capitalist state on entrepreneurial bases and at reshaping in innovative ways the relationships between business interests and the public sector. The latter approach, defined as 'roll-out' stage of neoliberalism in Peck and Tickell's terminology, has been advocated during the 1990s by the New Democrats and the New Labor Party led by Bill Clinton and Tony Blair in the United States and Great Britain, respectively.

Neo-progressive parties took the lead, therefore, in a second stage of the neoliberal 'revolution,' replacing the conservative parties dominating the first stage, in the United States as well as in their most influential allied countries, notably those belonging to the Atlantic Alliance that has remained unchallenged after the collapse of the Soviet Union. Having acquired this role, the progressive parties have engaged in a vast endeavor of self-legitimization in the eyes of business actors, by precipitously converting to the basic tenets of the neoliberal orthodoxy: the obsession for budget rigor leading in Europe to the adoption of a restrictive fiscal and monetary policy as the distinguishing trait of the newly founded European Union in 1992, the reduction of public spending in social assistance and, finally, most importantly in the context of post-Fordist capitalism, the flexibilization of the workforce. Unlike the conservatives, refusing the idea itself of society as a collectively organized entity and embracing the purest free market ideology, the center-left governments have sought to reconcile objectives which were considered mutually antithetic until a recent past. Combining the enhancement of social cohesion with the stimulation of economic competitiveness and turning the public sector into a more entrepreneurial and accountable organization have been distinguishing features of the so-called 'new liberal formulation' (Harloe, 2001). The 'Third Way' publicly announced by the British Prime Minister Tony Blair and theorized by sociologist Anthony Giddens (1998) came to represent the most consistent example of neoliberal formulation being proposed on the progressive side of the political spectrum as an

alternative to the ultraliberalism advocated by the conservatives. The emphasis placed on 'global governance' and transnational civil society, in contrast to the neoliberal aversion to 'big government' and social justice, alongside the attention paid to issues of environmental sustainability and cultural pluralism, in lieu of the conservative predilection for the integrity of the family and the nation, have been the essential principles of Giddens–Blair's Third Way (Peck and Theodore, 2001).

Within the sphere of urban government, apparently indissoluble beliefs and taboos received from the past shattered in the face of local and nationwide campaigns against petty and organized crime and the variety of phenomena of social deviance, including homelessness, drug abuse, and even 'art crimes' such as graffiti and writing. While urban administrations led by conservative mayors gave rise to highly mediatized repression campaigns against urban crime, such as most famously the 'zero tolerance' initiative adopted in the 1990s by the Mayor of New York Rudolph Giuliani (Smith, 1998), the center-left governments sought to restore their credibility in security policies; a field in which progressive parties were still conventionally associated with tolerant attitudes. In this vein, Prime Minister Tony Blair announced, in the political Manifesto of the New Labor in 1997, a new course of action against crime under the banner of the slogan: "tough on crime and tough on the causes of crime," which explicitly attempted at reconciling policies addressing issues of social exclusion and urban deprivation with measures to combat crime and deviance.

Broadly speaking, the second stage of neoliberalism in the 1990s testifies to an important redefinition of the ways in which capitalist cities are governed and administered. In the unified European space, these changes have taken form through institutional dynamics of multilevel governance, in which cities and regions play a crucial role, after the hollowing out of the state and of the institutions gravitating within its sphere (Jessop, 2004). In the public service sector, on the one hand, local and regional governments assume key roles in the governance process; on the other hand, however, subnational administrations externalize their prerogatives to other subjects of private or not-for-profit status, in line with the general trend of contractualization of social services, by which services are delivered on the basis of a contract signed between the providers (either within or outside the formal public sector) and welfare recipients. Job centers subcontracted to private companies or quasi-public agencies replace the old state-led employment bureaus, while similar processes of outsourcing occur in the health care services and other social assistance sectors organized at the local level with a view to achieve a modernized local welfare state based on dynamic local–central and public–private relationships (Cochrane, 2004). In times, in which economic and financial flows appear to be increasingly out of juridical and political control and in which the strategies of transnational firms and other 'foreign' investors are caught in a hardly decipherable chaos, large cities, and metropolitan areas – in their capacity to foster internationally competitive economies of agglomeration and diversity – are assumed to be crucial institutional arenas in the regulation (i.e., the deregulation and reregulation) of capitalist economies and societies (Brenner and Theodore, 2002). At the same time, owing to the reduced government spending and the fierce competition in obtaining public and private funds for economic regeneration policies and particularly for costly infrastructural projects, urban governments are compelled to devise a wide range of local economic development strategies: place marketing and promotion campaigns, mega-events, company subsidies, and the creation of free economic zones.

Neoliberalizing Urban Economies

In the described context of hegemonic and at the same time spatiotemporally variegated neoliberalism, two local economic regeneration schemes are particularly illustrative of the dominant approach to urban development: the 'Urban Enterprise Zones' policy, which was first carried out at the time of the Thatcher premiership and the Business Improvement Districts initiatives. The former, based on fiscal incentives and ambitious infrastructure projects, is designed to trigger economic development dynamics in declining and peripheral urban areas. In neocapitalist China, the creation of 'economic special zones' in the 1980s made a decisive contribution to the booming of its export-led economy, particularly in the southern coastal regions which have become the drivers of China's path of economic development: the industrial cities of Shenzhen, Dongguan, and Canton in the rampant Pearl River Delta region. The Business Improvement Districts policy, on the other hand, which has been embraced by local governments in a number of countries including Britain, Germany, New Zealand, and South Africa since the 1970s onward, focuses on the physical renewal and the aesthetic amelioration of attractive and potentially profitable urban districts (usually shopping and entertainment precincts located in downtown areas), using funds obtained from the self-taxation of local private firms, whose financial efforts are rewarded with the assignment of autonomous responsibilities in the management of the regenerated spaces (Ward, 2006; Cook, 2008).

Contemporary processes of urban and regional governance highlight the rise of relatively autonomous scales of economic and spatial regulation at the local level, but also the persistent influence of the national state in this realm, particularly in the East Asian context, but in different ways also in Western liberal democracies. In the unified European space, the last two decades have indeed seen the national state repositioning itself as a key actor in the coordination and the material structuring of the complex multilevel governance structure regulating the processes of urban and regional development (Brenner, 2004). This institutional context demands attention being paid to the ways in which neoliberal imperatives dictated by international and national politico-economic elites become incorporated into economic development strategies at the urban and regional levels, particularly in the form of public–private partnerships aimed at revitalizing local economies through the creation of technological districts, the abatement of local taxes, the demolition of obsolete housing, the redesign of residential spaces, the megaprojects of downtown and waterfront regeneration, the construction of iconic buildings, the invention of luxury and mass-consumption spaces, and the adoption of surveillance devices guaranteeing the safety of inhabitants and city users (Asian, European, and North American case studies are available in Olds, 1995; Moulaert et al., 2005; Orueta and Fainstein, 2008).

Outside the Western world, powerful think tanks and supranational institutions have made a decisive contribution to the diffusion of the approach to urban policy that has been described above. At the global scale, a crucial role has been played by the World Bank and the Organization for Economic Cooperation and Development (OECD). The World Bank's "corporate goals of reducing poverty, promoting market-based growth, building durable institutions, and protecting the environment" (World Bank, 2000, p. 40; *see also* World Bank, 1991) stem from a conventionally neoliberal understanding of economic development issues. From the standpoint of the Washington-based organization, cities are not to be considered as containers of social problems, let alone places where socio-spatial inequalities have to be addressed, but as 'engines' of economic growth, more precisely as centerpieces for processes of economic-relational networking reconnecting local economies to the global flows of capitals, commodities, information, and policy discourses (Theodore and Peck, 2012). In the emerging economies of the Global South, as a result, local elites are pressed with demands from international organizations for turning the major urban agglomerations into globalizing cities competing with their Western counterparts. Even in cities located in what was previously labeled as 'Third World,' the 'urban question' is no longer concentrated on housing issues and the allocation of adequate services for the local population, but on the optimization of local economic productivity. The currently common wisdom on development issues holds that even antipoverty initiatives – which used to have priority in the urban policy agenda until a recent past – have to be combined with strategies of economic growth.

The link between antipoverty and economic growth policies is justified not only along discursive lines (for instance, as a way to avoid parasitic social assistance), but also by reference to structural changes within urban development dynamics. In the cities and metropolitan areas in the Global South, economic growth processes and the regeneration of large urban areas have been accompanied by the proliferation of informal settlements, variously defined slums, favelas, bidonvilles, shantytowns, depending on the geographical–linguistic context. This 'planet of slums' (Davis, 2006) has taken shape also as an indirect consequence of selective and elitist strategies of urban development, concentrated on a limited set of 'competitive' urban spaces. In the discursive politics of neoliberalism, even slums and favelas are portrayed as 'opportunities' for economic development, waiting to exploit the potential of their entrepreneurial talents (Mukhija, 2003).

Reproducing Neoliberalism

A result of the dynamics that have been shortly described and analyzed in the previous section has been the global expansion and circulation of neoliberalism, which has adapted to the varying (geographically and historically) configurations of post-Fordist urban capitalism. Many authors have approached the urbanization of neoliberalism through the lens of the 'new urban politics' originally identified by Kevin Cox and other critical urban geographers (Cox, 1993; Cochrane, 2007). The characteristic, and the ambiguity, of urban neoliberalism rests on its ambivalent relationship with the public sector and the state in particular. On the one hand, in line with the tenets of classic liberalism and its more recent formulations in the last quarter of the twentieth century, supporters of urban neoliberalism postulate the retreat of the state from the socioeconomic realm, advocating an involvement of private actors within the institutions of urban and regional governance; on the other hand, supporters of neoliberal policies do not hesitate to exert pressure on national governments when it comes to obtain financial support for megaprojects and international events capable of fostering the so-called 'urban boosterism' (Harvey, 1989).

Apart from internal contradictions as well as the relentless attempts to mediate between conflicting interests, the strength of urban neoliberalism rests on its capacity to incorporate all sorts of urban problems and issues (social, economic, and environmental) into the seductive domain of spatial competitiveness and economic growth, proposing policies flexibly adapting to a variety of geographical contexts. What can be defined the 'politics of the mime' – namely, the alternatively passive or creative imitation of successful models of urban growth – has expanded across the globe, albeit this process has occurred in varying forms and with contrasting outcomes (Rossi and Vanolo, 2012). As soon as the depressive effects of the geopolitical and monetary crises of the 1970s vanished and the Japanese challenge to the Western hegemony on technology and business management unraveled, 'ideas from America' became again predominant. As a result, since the 1980s strategies of urban economic development and restructuring in the United States have acquired a renewed leading role, offering success stories of innovation and entrepreneurship in a number of advanced sectors such as finance, business administration, information, and communication technologies. In an increasingly competitive and interconnected environment such as that of the globalizing capitalist economy, the rapidity and intensity of economic and spatial changes being observed in the North American context have forced those governing cities and regions in other contexts to accelerate the implementation of regeneration policies and broader projects of urban development. As Peck and Tickell (2002) have underlined, the length of time covering the manifestation of an urban issue, the selection of objectives and priorities, the mobilization of institutions and financial sources, the organization of projects and urban planning initiatives and, finally, their implementation has increasingly shortened, inducing local elites to rely on ready-made policy recipes ('off-the-shelf solutions' as the two authors put it), more easily implementable and less likely to be contested by the local population in comparison to strategies formulated at the local level.

For the reasons explained above, neoliberalism has succeeded in reproducing and 'territorializing' itself in apparently efficient and even creative ways, rapidly migrating from one place to another across the globe. In doing so, it has drawn on the contribution of a variety of powerful agents and intermediaries: technocratic elites, think tanks, global consultants, political networks, and development gurus (such as Richard Florida and Michael Porter, the theorists of the urban 'creative class' and the 'competitive advantages' of the inner city, respectively). The planetary circulation of presumably winning ideas and policy solutions is conventionally labeled as 'policy transfer' within the mainstream political sciences, while it is alternatively understood in terms of 'policy mobility' by critical

urbanists pointing to the effect of reinvention associated with the process of circulation (McCann, 2010; Peck, 2011). The phenomenon of policy mobility and transfer is related not only to strategies of growth-led development and governance (such as in the cases of the Special Economic Zones and the Business Improvement Districts policies), but also to issues and problems firmly anchored in local and institutional specificities, such as poverty, deviance, social marginality, and urban criminality (Wacquant, 1999). Using a metaphor drawn from evolutionary sociobiology, it can be observed what happens when an intrinsically complex system (such as the city or the world economy) reduces its own 'political biodiversity' (i.e., the variety of conceptual and operational tools normally used in order to identify policy issues and formulate appropriate strategies to tackle them), becoming more vulnerable and exposed to the risks associated with the reduction of viable options for action (the selection mechanisms in the evolutionary terminology). An illuminating example of the dangers associated with the reduction of complexity generated by the global expansion of neoliberal urbanism is that of the financial crisis that hit the world economy in 2008 and 2009. Owing to the role played by the housing finance sector in triggering an economic slowdown in the United States that has rapidly traveled toward other advanced capitalist economies, today's cities appear to be crucial sites in which the limits and the contradictions of neoliberal capitalism and globalization can be observed and critically scrutinized.

The Global Recession: A Crisis of (Urban) Neoliberalism?

The intimate relationship linking capitalism, the housing sector, and processes of urban development has come to the fore in an extraordinarily visible fashion over the last three decades or so. First, the so-called 'financialization' of the global economy (the steady increase in financial transactions at a world scale and their autonomization from the 'real' economy) has played a key role in the ascent of established or emerging global cities, such as London and New York in the West, and Shanghai, Hong Kong, Singapore, Mumbai and Dubai in Asia; in addition, before the crisis, the housing boom had been the engine of economic growth after the end of the short period of contraction that followed the bursting of the New Economy bubble (the economy based on 'dotcoms' firms which expanded between 1995 and 1999). The noticeable but also virtual profits linked to the financialization of the economy, alongside the vertiginous rise of property values, have generated – during the relatively short golden age of post-cold war neoliberalism, the two decades between the mid-1980s and the first half of the 2000s – widespread illusions and expectations of unlimited wealth accumulation until the 2008–09 financial crisis.

The financialization of the economy, which has been brought about by neoliberal globalization and the dismissal of Keynesian economic policies, has sparked a trajectory that has eventually led to the economic slump of 2008–09 and the subsequent recession. The process of financialization has produced an unprecedented availability of capitals, which have been partly reinvested in the mortgage market, resulting in the growing expansion of the real estate sector. In the early 2000s, the United States, and particularly the southern and western states (the so-called 'Sun Belt' which had been at the forefront of the post-Fordist transition), such as California, Texas, Florida, witnessed a steady rise in housing prices, as a consequence of the expansion of homeownership due to the illusory increase in mortgage opportunities. Related phenomena of rising demand in the housing market have been observed in those European countries that have laid out permissive regulatory frameworks on financial services and consumer credit, such as Spain, Ireland, United Kingdom, and Iceland. These countries, along with the American states that were in the forefront of the housing bubble, have been those that most have suffered the consequences of the 'credit crunch' that hit the world economy in 2007–2008. A variety of social groups have been affected by the economic downturn, especially those that had the illusion of attaining a higher standard of life thanks to easier access to homeownership and to a number of goods (not always strictly necessary) purchased through consumer credit.

The push for homeownership has been actively encouraged by the deregulation of mortgage markets in the United States and in many European countries as well. Since the early 1990s, the acceptance policies of banks have become increasingly lenient, and credit limits (i.e., the maximum amount that can be borrowed through a mortgage) have expanded (Aalbers, 2008). The illusion of a relentlessly expanding homeownership is, therefore, at the origin of the subprime mortgage crisis in the United States. Subprime mortgages are riskier loans, in many cases, refinances, offered at higher (predatory) interest rates to economically vulnerable and potentially insolvent clients: low-income individuals belonging to ethnic minorities and other disadvantaged groups, frequently employed on a casual basis and with a background of credit default (Wyly et al., 2007). High-risk 'predatory' loans were introduced in the 1990s, preparing the ground for the housing bubble of the subsequent decade. In 2006, the apparently unlimited expansion of the mortgage market started slowing down, giving rise to a set of interrelated negative phenomena, eventually leading to a downward spiral: growing insolvencies by mortgage borrowers, foreclosure proceedings, increase in housing abandonment at the neighborhood level, crisis, and in some cases bankruptcy of credit institutions, fall of housing prices and depreciation of property values. In September 2008, the bankruptcy of Lehman Brothers, one of the largest and oldest financial firms in the United States, triggered by the subprime mortgage crisis, created a banking panic which was followed by the global economic recession.

The economies of cities and metropolitan regions that in previous years had taken the lead in the process of globalization and neoliberalization have been seriously affected by the credit crunch, the crisis of the housing market and of the wider economy: from established global cities (New York, Los Angeles, London) to globalizing cities (Dubai, Shanghai, Singapore) where spectacular megaprojects were underway when the crisis began, to the new centers of urban Europe such as Dublin, Barcelona, Manchester, and even the quiet Reykjavik have faced a deep depression of the economy, with the closure of several firms and commercial activities, the generation of new reserves of unemployed and working poor, while a number of urban

megaprojects have been suspended. In the United States, which has been the epicenter of the global economic shock – after having been at the core of the organizational and technological 'revolution' of post-Fordism and of the process of financialization – it is not only the private sector that has suffered the consequences of the downturn. With increasingly passive local budgets owing to the risky investment operations undertaken in the years of the financial boom and as a result of austerity measures being adopted at the national level, the administrators of several cities in the United States and across the advanced capitalist world have been forced to drastically reduce the supply of important services (transportation, health care, cultural events) so as to manage to repay the debts and to meet fiscal consolidation targets.

Whereas orthodox economists are blamed for not having predicted the economic and financial crisis, but also for having actively contributed to foster the belief of self-regulating markets, the expansion and the subsequent cataclysm of urban capitalism in the neoliberal era were prophesied by David Harvey and those sociologists and geographers who, drawing on his pioneering studies, have analyzed in detail and at the same time have denounced the destructive link between finance, capitalism, and urban development (Aalbers, 2012). More generally, the present global recession is commonly perceived as the 'crisis of neoliberalism,' namely as the outcome of the contradictions inherent in the neoliberal strategy of capitalist development and related macroeconomic policies (see, for instance, Duménil and Lévy, 2011; Overbeek and van Apeldoorn, 2012), even though critical commentators lament the fact that powerful economic actors have managed to retain and even increase their influence and wealth thanks to state bailouts and the unchallenged dominance of free market ideas among mainstream policy makers and politicians (Crouch, 2011). The coming years will show, therefore, whether this structural crisis will stimulate a shift in the dominant paradigm of economic-political regulation or it will just reassert the power of neoliberalism on novel material and discursive bases.

Abstract

Virtually all countries report population and other data as urban or rural, but specific definitions vary greatly as to the geographic units used and how populous an urban place must be. Many countries recognize urban as including overflow and suburbs outside municipal limits, giving rise to additional definitions such as urbanized areas and metropolitan areas. This article discusses the US definition of urban and its evolution, summarizes the US metropolitan definition, and compares the urban definitions of the 40 countries with the largest urban populations, with special attention to China.

Introduction

Studies of cities and urbanization rely on the availability of relevant statistics, especially censuses and other data from national, state, and municipal governments. Most countries publish a range of statistics for their cities, and many do so for aggregates identified as urban and rural. However, what is termed a city varies greatly across countries and sometimes even within countries, and there is little international consistency in what is defined as urban. The United Nations Population Division publishes estimates and projections of urban population for the world and individual countries, but in doing so it accepts each country's own particular urban definition and has not made any recent effort to establish an international standard.

This wide variation in official census definitions of urban is not due primarily to differences in the concept of what constitutes an urban locality. In nearly all countries, the adopted definition of urban seeks to identify a high-density concentration of nonagricultural population, typically with some kind of municipal government. However, the minimum population size required for recognition varies widely by country.

Countries also differ in how they delimit the individual urban place, which may be an administrative unit, such as a city or commune, or may be defined with a nonadministrative boundary. Each alternative has some advantages; choice of an administrative unit generally will maximize the amount of statistical data available for the place, from censuses, other government-produced statistics, and private sources. On the other hand, places defined with nonadministrative boundaries may more precisely represent the place as a dense concentration of nonagricultural population, but be less convenient as to data availability and public recognition (Gibbs, 1961: Part I; Goldstein and Sly, 1974; Arriaga, 1975).

Besides recognizing urban places as a category, many countries have defined larger entities such as urban areas, urbanized areas (UAs), and metropolitan areas (MAs). These concepts developed early in the twentieth century, as the population and geographical extent of urban development overflowed the boundaries of most large and many small cities, leaving the city administrative unit underbounded and less representative of the actual urban concentration. But just as with urban places themselves, definitions of these larger urban entities have varied greatly across countries.

The following sections of this article discuss the definition of urban used in the United States, the US metropolitan definition, and the urban and metropolitan definitions currently used by some larger countries. The concluding section, by the second author, presents the urban definition used in China.

United States: Definitions of Urban

Official concern with determining urban and rural populations in the United States can be traced back to the 1850 decennial census. A statistical atlas of 1874 and the 1880 census recognized municipalities of at least 8000 population as urban and also presented data for an alternative threshold of 4000. A supplementary analysis of the 1900 census was the first that officially designated places of 2500 or more as urban (Walker, 1874; Truesdell, 1949). That size threshold for urban status has been retained in every subsequent US decennial census, although no extended justification for it has been offered.

However, besides the changes in threshold there have been significant changes in the choice of geographic unit to which the population threshold is applied. Moreover, the US experience illustrates how the nature of a country's administrative divisions can affect its definition of urban territory.

US Incorporated Municipalities

Under the federal structure of the United States, major differences in the characteristics of municipalities appear across states, because each state creates and oversees its own administrative subdivisions. All states have counties or county equivalents, and subcounty units of various degrees of local self-government, collectively referred to as minor civil divisions (MCDs). Incorporated municipalities exist in all but one state (Hawaii); they are variously termed cities, towns, boroughs, or villages. In most states, they are associated with locally recognized nonagricultural population concentrations and contain relatively little open-country population.

These 'incorporated places' (the Census Bureau term) comprise only a small share of the total US area, while the

remainder is sometimes referred to as 'unincorporated.' In 2010, 19 533 incorporated places contained 192.0 million people or 62.2% of the US population, but only 122 236 m^2 or just 3.5% of the land area. Many incorporated places are very small, with roughly half having fewer than 1000 residents (U.S. Census Bureau, 2012: Tables 8, 9, and 38).

The six New England States (Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont) diverge from this pattern. Here, the basic subdivisions are incorporated municipalities termed cities or towns, which collectively comprise all or most of the inhabited area of the state. Unlike the typical incorporated place in the other states, in New England most towns and some cities include considerable open-country territory along with at least one high-density concentration of population.

This New England pattern in which local municipal-type governments include rural as well as urban territory somewhat resembles the commune-type pattern found widely in Europe, although the New England units average much larger in extent than typical communes. It dates from the first period of English settlement in the early 1600s. While some other Northern states have subcounty municipal-type governments, commonly termed townships, they also have many incorporated municipalities like those of the remaining states – in some cases within and subordinated to the townships. Among these states are New York and Wisconsin, where the entities commonly called townships are officially termed towns.
